readme            This file.
```

I've provided my assembler library for those who still use Acylon C (like me). It has been modified since the last release. Basically adopting standard C library names and parameter conventions.

List.c provides generic doubly link list routines that are used by Memory.c to mantain the free list. Runtime.h contains all the data types used and function prototypes.

Reference for that helped in the development of Memory.c:

1) Knuth vol 1, pg 435-451
2) Kernighan & Ritchie "The C Progamming Language" pg 173-177

Memory.c uses unsigned int which limits memory requests to Mnew in the range 1-65534. This is because Acylon C doesn't support unsigned long. Also the application for which this was written did not require large memory blocks. The source could be modified to fix this limitation if compiled under MWC or GNU CC.

Notes:

1) All source used tabstops = 4
2) Development site was Colour Mega ST 2
3) Development software: BDT Micro C-Shell, BDT Make, LV, Acylon C, MadMac Assembler, Aln Linker

Any inquires send mail to:

achowe@watmsg.waterloo.edu

Disclaimer: The software provided has been written out of need and a desire to learn. Everything has been tested, yet things can go wrong (ie. typos). I refuse to take any responsablity for damage that could have resulted from the use of this code. I have enough trouble finding a decent pizza at 1 am.

PLEASE PLEASE test code independantly till you get that warm feeling like
when you p__s in a pool :)

Anthony C. Howe

Submitted-by: cs.buffalo.edu!sigmast!dgy (Dave Yearke)
Posting-number: Volume 1, Issue 76
Archive-name: sttar

[This arrived in the form of three shar files inside an arc file; I unpacked
 the arc file and sharred the shar files.  The result is that you'll have to
 unshar four times to get everything out.  Let me know if this causes any
 problems. -sg]

This is an implementation of "tar" for the ST.  Questions and comments
should be directed to Carl Barron at sigmast!brass!carl_barron.

X    NAME  ftw - walk a file tree
X
X    SYNOPSIS
X
X#include <ftw.h>
X
Xint
Xftw(directory, funcptr, depth)
X    char *directory;
X    int (*funcptr)();
X    int depth;
X
X#include <stat.h>
X
Xint
Xfuncptr(item, sb, flag)
X    char *item;
X    struct stat *sb;
X    int flag;
X
X
X    DESCRIPTION
X
X    Ftw walks through the directory tree starting from the indicated path .
XFor every entry it finds in the tree, it calls the user-supplied funcptr with
Xthe calling sequence given in the synopsis above.  The first argument is the
Xfull pathname of the entry (rooted from the directory parameter given to ftw );
Xthe second argument is a pointer to the stat (2) structure for the entry;
Xand the third argument is one of the #define's in the header file.
XThis value will be one of the following:
X
X    FTW_F     Item is a normal file
X    FTW_D     Item is a directory
X    FTW_NS    The stat failed on the item
X    FTW_DNR   Item is a directory which can't be read
X
X
XNote, however, that FTW_F is a misnomer; anything other than directories
Xare (e.g., symbolic links) get the FTW_F tag.
X
X    Ftw recursively calls itself when it encounters a directory. To avoid
Xusing up all a program's file descriptors, the depth argument specifies the
Xnumber of simultaneous open directories to maintain.  When the depth is
Xexceeded, the routine will become noticeably slower because directories are
Xclosed in ``most-recently-used'' order.
X
X    To stop the tree walk, the user-supplied function should return a
```

```
Xnon-zero value; this value will become the return value of ftw .  Otherwise,
Xftw will continue until it has scanned the entire tree, in which case it will
Xreturn zero, or until it hits an error such as a malloc (3) failure, in which
Xcase it will return -1.
X
X    Because ftw uses dynamic data structures, the only safe way to exit
Xout of a tree walk is to return a non-zero value.  To handle interrupts, for
Xexample, mark that the interrupt occured and return a non-zero value, don't
Xuse longjmp (3) unless the program is going to terminate.

X
X    NAME ndir - portable directory reading routines
X
X    SUMMARY
X
X    #include <ndir.h>
X
X
X    DIR *opendir(name)
```

```
X        char *name;
X
X    struct direct *readdir(dirp)
X        DIR *dirp;
X
X    void closedir(dirp);
X        DIR *dirp;
X
X    void seekdir(dirp,where)
X        DIR *dirp;
X        long where;
X
X    long telldir(dirp);
X        DIR *dirp;
X
X
X    Opendir() opens a dirctory for reading and returns a pointer to a DIR
Xfor this directory.
X
X    readdir() reads the next entry in the directory and returns a pointer
Xto a struct direct for this readding.
X
X    closedir() closes the directory.
X
X    seekdir() sets directory read to a given place in the directory.
X
X    telldir() returns the place of the next read in the directory.
X
X    struct direct is defined in the header file as:
X
X    struct direct
X    {
X        long d_ino;        /* inode number of entry */
X        short d_reclen;        /* length of this record */
X        short d_namlen;        /* length of the string d_name */
X        char d_name[MAXNAMLEN+1];/*basename -must not be longer than
X                        MAXNAMLEN */
X    };

Xint (*sorter)();
X
X
Xint
Xalphasort(d1, d2)
X    struct direct **d1;
X    struct direct **d2;
X
```

```
X    DESCRIPTION
X
X    Scandir reads the directory name and builds a NULL\-terminated array
Xof pointers to the entries found in that directory.  This array is put into the
Xlocation pointed to by the list parameter.
X
X    If the selector parameter is non-NULL, it is taken to be a pointer to
Xa function called with each entry, to determine whether or not it should be
included in
Xthe returned list.  If the parameter is NULL, all entries are included.
X
X    As an added feature, the entries can be sorted (with qsort (3))
Xbefore the list is returned.  If the sorter parameter is non-NULL, it is passed
Xto qsort to use as the comparison function.  The alphasort routine is provided
Xto sort the array alphabetically.
X
X    The array pointed to by list and the items it points to are all space
Xobtained through malloc (3), and their storage can be reclaimed as shown in the
Xexample below.
X
X    "EXAMPLE"
X
X    Here is a small ls (1)\-like program:
X
X#include <stdio.h>
X#include <types.h>
X#include <stat.h>
X#include <ndir.h>
X
Xextern int alphasort();
X
Xstatic int
Xfilesonly(e)
X    struct direct *e;
X{

RAYMOVI.PRG

RAYMOVI.PRG renders 3-dimensional scenes in a world of reflective and refractive spheres, using ray tracing techniques. Animated sequences of frames can be generated, showing reflective balls linked and bouncing in a gravitational field. They resemble a string of bouncing pearls.

RAYMOVI.PRG runs only on a color ST in low resolution. 1 Meg is required to generate images with resolutions greater than one ray per pixel or for replay of movies from RAM. Operation with only 512K is possible, but will produce slightly aliased pictures (one ray per pixel) which can only be displayed statically, slowly from floppy, or from hard disk (if you have a disk blaster program).

The files in RAYMOV2S.SHAR, the source sharfile, are:

```
C Sources:    BLASTRAM.C, MAIN.C, WNDOWS.C, FILE.C, MOVIE.C, SHADE.C,
         FIND.C, SUPPORT.C
Include files:     RTD.H, STYLE.H, COLORS.H, EXTERN.H
Pgm Generation: MAKEFILE, BLASTRAM.LNK, RAYMOVI.LNK
RAYMOVI.DOK   documentation
PEARLS        the numeric description of an interesting scene
```

RAYMOVI was last compiled with ALCYON. The MAKEFILE and *.LNK are (therefore) pretty crufty. Use them accordingly.

RAYMOVI requires an 8K stack. Modify your copy of gemstart.s (or whatever defines your stack size) appropriately.

chmod 0600 PEARLS || echo "restore of PEARLS fails"
sed 's/^X//' << 'SHAR_EOF' > RAYMOVI.DOK &&
X             RAYMOVI.PRG
X
X   RAYMOVI.PRG renders 3-dimensional scenes in a world of reflective and
Xrefractive spheres, using ray tracing techniques. Movies formed from
Xsequences of frames can be generated, showing reflective balls linked and
Xbouncing in a gravitational field. They resemble a string of bouncing pearls.
X
X   The amount of computation required to produce one ray traced image is
Xenormous -- on an ST it is measured in hours. To get animated effects,
Ximages must be precomputed in (overnight) batch runs. RAYMOVI provides the
Xability to save sequences of images on disk in Degas PI1 format, for later
Xreplay by BLASTRAM.TTP (also included).
X
X   RAYMOVI.PRG generates a low resolution approximation of each picture first,
Xfollowed by refinement to successively higher resolutions. In this way,
Xa rough image is seen quickly for (somewhat) interactive debugging. Scenes
Xcan be changed without recompilation of RAYMOVI.PRG -- the size, position,
Xvelocity and optical properties of the balls in the scenes are specified
Xnumerically in the initialization files.
X
X   The ray tracing heart of RAYMOVI was taken from net.sources, documented
XFredrich Knauss of University of California, San Diego. I've ported it to
Xthe ST, added animation, (primitive) color, and the various other features
Xyou see here. I place RAYMOVI in the public domain, for non-comercial use only.
X
X   RAYMOVI.PRG runs only on a color ST in low resolution. 1 Meg is required
Xto generate images with resolutions greater than one ray per pixel or for
Xreplay of movies from RAM. Operation with only 512K is possible, but will
Xproduce slightly aliased pictures (one ray per pixel) which can only be
Xdisplayed statically, slowly from floppy, or from hard disk (if you have
Xa disk blaster program).
X
X   The rest of this document contains sections entitled Getting Started,
XConfiguration File Format, and Checkpointing. The sources are available
Xupon request. With enough interest I could post them.
X
X
X
X             GETTING STARTED
X
X   The screen must be set to low resolution mode before running RAYMOVI.PRG.
XOnce started, '?' will give help. Keys 'r' reads and 'w' writes the current
Xscreen using the current disk file, whose name is displayed in the upper
Xleft corner of the screen. Key 'e' exits. The average number of rays shot
Xthrough each pixel is also displayed in the margin and updated as the
Xcomputation develops.
X
X   After unpacking RAYMOVI, the first logical thing to do is to start it up
Xwith the configuration file PEARLS.  After a few minutes, you'll see
Xa rough image, with the resolution increasing as you watch. You might
Xwait an hour or so to get complete development, but if you get bored, hit
```

```
Xthe 'r' key. This will read the one pre-computed picture PEARL001.PI1 which
Xcame in the "arc".
X
X   Now put RAYMOVI aside until you are willing to dedicate a large chunk of
XST time to make a movie. When you have 10-20 hours free, start RAYMOVI,
Xagain with PEARLS. (Before you start, be sure you have a few hundred K
Xfree on the disk for the images which will be produced.) To view the movie
Xproduced, exit ('e') and start BLASTRAM.TTP, supplying the argument
XPEARL in the dialog box. With BLASTRAM running, type '?' for help.
XCheckpointing may be used if you wish to add more frames to the movie.
X
X
X
X             CHECKPOINTING
X
X
X   Since RAYMOVI.PRG runs are so long, checkpointing is important. (Actually
XI put it in because my sons rebooted the ST at 3:00 every day after school!).

sed 's/^X//' << 'SHAR_EOF' >> RAYMOVI.DOK
XThus following the completion of every frame, RAYMOVI saves the current
Xconfiguration on the disk so that if the computation of the next frame
Xis interupted, it may be restarted.  The checkpointing information
Xis written in a file named CHECKPT, in configuration file format. Starting
XRAYMOVI with CHECKPT will continue an interupted computation, redoing
Xonly any work which was in progress on the interupted frame.
X
X
X
X             CONFIGURATION FILE FORMAT
X
X
X   The following section discusses the format of the configuration files,
Xwhich specify initial ball positions, velocities and optical properties,
Xas well as lighting and viewing perspectives, picture resolution, and gravity.
XThe configuration file name to be used is specified initially with a dialog.
XThe file is then read line at a time. The character in column 1 specifies the
Xmeaning of the rest of each line. Lines may be up to 200 characters long. Lines
Xbeginning with whitespace are comments. The following other formats are
Xsupported:
X
X
X
X     - - - 'p' Format: - - -
X
Xspecifies the physical size and velocity of a ball. There are 7 properties
Xrequired for each ball, and they all must be specified on one line in the
Xfollowing order:
X
X (1) x coordinate of center         (2) x velocity
X (3) y coordinate          (4) y velocity
X (5) z coordinate          (6) z velocity
X (7) radius
X
XSome Notes:
X A) In the coordinate system used, Y is upward, X is to the right, and Z
X    is depth (increasing Z moves farthur away).
X B) Balls will bounce off the floor (the plane Y == 0) and an invisible
X    viewing port (the plane Z==0). Be sure to start them so that the whole
X    extent of the ball is above the floor and farther away than the
X    invisible viewing port.
X C) If balls start out overlapping, they will stick together.
X    This turned out to be a serendipitous bug in the bounce algorithm,
X    and produces the string of pearls from which PEARLS gets its name.
X D) The current version is compiled for up to 15 balls maximum.
```

```
X
X   The first p-format statement in the file defines the "first" ball RAYMOVI
Xknows about, the second the second and so on. Here are 6 balls which
Xform an interesting scene:
X
X   x     vx      y     vy    z      vz   radius
X  (1)    (2) (3)    (4)   (5)    (6)  (7)       (see (1)-(7) above)
Xp 195.0,-20, 130.0, 0,    250.0, 10,  30.0    these are the 4 linked balls:
Xp 150.0, -5,      100.0, 20,   250.0, 10,  30.0        "
Xp 105.0,  5,  70.0, 20,   250.0,-20,  30.0         "
Xp  60.0, 20,  40.0,  0,   250.0,-20,  30.0         "
Xp   0.0,-10, 300.0, 20,   600.0,  0, 300.0    this is the big ball
Xp 200.0,  2,  50.0,  5,    60.0, 30,  50.0    a medium size (lone) ball
X
X
X
X
X     - - - 'o' Format: - - -
X
Xspecifies the optical properties of a ball. The following 8 properties
Xmust be put on one line, and in order:
X
X (1) index of refraction
X
X (2) amount of refraction (transparent)
X (3) amount of reflection (mirror)
X (4) amount of diffuse light (omnidirectional)
X (5) amount of ambient light (from light source)
X
X (6) surface color redness
X (7) surface color greenness
X (8) surface color blueness
X
X
XSome notes are in order to make realistic objects:
X A) All parameters should be positive or zero.
X B) Items (2) through (5) should sum to less than 1.0
X C) Surface colors (6) through (8) modulate the effect the diffuse and ambient
X    reflective properties defined by (4) and (5). None should be greater than
X    1.0.
X C) Due to the size of the ST's color palette, surface color items (6)
X    through (8) are constrained to be patterns corresponding to one of the
X    following three colors:
X
X        white:        (6) == (7) == (8) == 1.0
X        red:     (6) == (7) == 1.0, (8) == 0.0
X        blue:         (6) == 0.0, (7) == (8) == 1.0
X
X
X   The i'th 'o' Format line refers to the same ball as the i'th 'p' Format line.
XHere are the optical properties for the scene:
X
X  (1)  (2)  (3)  (4)  (5)    (6) (7) (8)
```

```
Xo 0.0, 0.0, 0.3, 0.6, 0.1,   1.0,0.0,0.0   diffuse red, somewhat reflective
Xo 0.0, 0.0, 0.6, 0.3, 0.1,   1.0,1.0,1.0   reflective, somewhat white
Xo 0.0, 0.0, 0.9, 0.0, 0.1,   1.0,1.0,1.0   reflective, some ambient
Xo 0.0, 0.0, 0.0, 0.8, 0.2,   1.0,0.0,0.0   diffuse red, some ambient
Xo 0.0, 0.0, 0.7, 0.1, 0.2,   1.0,1.0,1.0   reflective and ambient (the big one)
Xo 1.6, 0.8, 0.0, 0.0, 0.2,   1.0,1.0,1.0   refractive
X
X
X
X
X     - - - 'v' Format: - - -
X
Xspecifies the viewpoint of the display. x, y, and z values are required.
X
Xv 215.0,     100.0,       -550.0
X  |     |         z coordinate of viewpoint
X  |     y coordinate of viewpoint
X  x coordinate of viewpoint
X
XAll rays start at the viewpoint and pass through a rectangle in the Z=0
Xplane. The rectangle is sized according to the size of the screen -- namely
Xon a 320x200 low resolution screen, it is defined by 0.0 < X < 320.0 and
X0.0 < Y < 200.0. (Actually, borders eat a few pixels on all sides.)
X
X
X     - - - 'l' Format: - - -
X
X   specifies the location of the lightsource, and its diameter. Like before
Xits x, y, and z coordinates, now followed by the diameter of the light.
X
Xl 150.0,     950.0,          0.0,        100.0
X
X
X     - - - 'r' Format: - - -
X
Xspecifies the resolution of the picture to be produced, in Rays projected
Xthrough each Pixel, followed by the color schema index, a number from 1
Xthrough 3.
X
Xr .20, 3
X
X   The inputted value of Rays Per Pixel will be rounded up to the next
Xgreater power of 4.0. Thus in the line above, the .20 will be rounded up
Xto (4.0)**(-1) = .25.
X
X   The time to compute images varies linearly with the resolution (Rays Per
XPixel) chosen. The constant of proportionality varies greatly depending on
Xthe complication of the scene, but for the 6-ball scene here on a 520ST:
X
X      .0625 rays per pixel    4 min
X      .25 rays per pixel     15 min
X     1.0 rays per pixel       1 hr
X     4.0 rays per pixel       4 hrs
```

X   16.0 rays per pixel   16 hrs
X
XI tend to use .25 rays per pixel to experiment with positions and velocities,
Xsince one can generate a couple dozen frames overnight. Once the positions
Xlook good, a few nights of 4.0 rays per pixel produces good looking images.
XI can tell the difference between 16.0 and 4.0 rays per pixel (sort of) but
Xit is hardly worth the time it takes. 0.625 is skimping, but its quick.
X
X
X   The color index specifies how the 16 colors of the low resolution monitor
Xare divided amongst hues and saturation. Three values are accepted currently:
X
X   1:   white   16 saturations
X   2:   white, red   8 saturations each
X   3:   white, red, blue   6 saturations each
X
XAlthough the ray tracing algorithm computes arbitrary red/green/blue hues,
Xthe palate limitations of the ST prohibit their display.
X
X
X
X
X   - - - 'g' Format: - - -
X
Xspecifies the strength of gravity, the mutual attraction between balls,
Xand if balls bounce (in order). The following is realistic:
X
Xg 32.0, 0.3, 1
X
X(Note: if balls do not bounce, they may occupy the same space. In that case
Xthe current the ray tracing algorithm does not properly render refractive
Xobjects.)
X
X   - - - 'f' Format: - - -
X
Xspecifies the first 5 characters of the filename to be used to save
Xcompleted pictures. (The rest of the name is the frame sequence number,
Xand the suffix .PI1) Also specified are the starting and ending frame
Xnumbers to be computed (positive integers less than 999).
X
Xf pearl, 1, 20
X
Xgenerates 20 frames on the disk, labeled PEARLL001.PI1 through PEARL020.PI1.
XAt 32K per frame, that will just about fill a double sided drive.
X
X
X
X   --------------
X
X   Thats it for now. Tell me of you ventures, send me interesting
Xconfigurations you find, and enjoy!
X
X

X             RAYMOVI.PRG
X
X   RAYMOVI.PRG renders 3-dimensional scenes in a world of reflective and
Xrefractive spheres, using ray tracing techniques. Animated sequences of
Xframes can be generated, showing reflective balls linked and bouncing in
Xa gravitational field. They resemble a string of bouncing pearls.
X
X   RAYMOVI.PRG runs only on a color ST in low resolution. 1 Meg is required
Xto generate images with resolutions greater than one ray per pixel or for
Xreplay of movies from RAM. Operation with only 512K is possible, but will
Xproduce slightly aliased pictures (one ray per pixel) which can only be
Xdisplayed statically, slowly from floppy, or from hard disk (if you have
Xa disk blaster program).
X
X        ---------------------------------------------------
X
X   The files in RAYMOV2S.ARC, the source arc, are:
X
XC Sources:   BLASTRAM.C, MAIN.C, WNDOWS.C, FILE.C, MOVIE.C, SHADE.C,
X         FIND.C, SUPPORT.C
XInclude files:    RTD.H, STYLE.H, COLORS.H, EXTERN.H
XPgm Generation: MAKEFILE, BLASTRAM.LNK, RAYMOVI.LNK
XRAYMOVI.DOK  documentation
XPEARLS       the numeric description of an interesting scene
X
X   RAYMOVI was last compiled with ALCYON. The MAKEFILE and *.LNK are
X(therefore) pretty crufty. Use them accordingly.
X
X   RAYMOVI requires an 8K stack. Modify your copy of gemstart.s (or
Xwhatever defines your stack size) appropriately.

Subject: v01i080: gstlink -- Faster linker for GST object files
Keywords: C
Message-ID: <5804@saturn.ucsc.edu>
Date: 20 Dec 88 09:19:49 GMT
Sender: usenet@saturn.ucsc.edu
Lines: 1322
Approved: koreth@ssyx.ucsc.edu

Submitted-by: uunet!unido!sbsvax!roeder (Edgar Roeder)
Posting-number: Volume 1, Issue 80
Archive-name: gstlink

[The executable is being posted to the binaries group. -sg]

This program was published in the german magazine ST-Computer (3/88 if i
remember correctly). It is a new (faster, better) linker for the GST BIN format
(used by Lattice-C, Metacomco-Pascal, ...).  It supports the same options like
the default GST-linker (-with, -prog, -sym, -debug, -list, ...) plus several
new ones:
     -sec = generate seperate TEXT, DATA and BSS segments and leave BSS
```

```
            out of the generated program
     -nosec    = generate the same output as the old linker
     -mem = specify internal memory size used for linking the program in
            RAM (yes, therefore it's so fast)
     -buf = specify buffer size used to read in libraries
```

If you use '-sec' the programs will be much smaller than with the original linker from GST.

A friend (of a friend of a ...) hacked this code into the computer so it's poorly documented. But the linker seems to be well debugged, so you should not need to alter the code.

The compiled program uses extended argument passing via either PBP/ARGV (as proposed by Allan Pratt) or ARGV with io_vector like the MWC msh. The use is triggered with the presence or absence of PBP in the environment (and of course the right pointer should be there). I have not included the modified startup.asm for Lattice-C (but if there is some interest, ...) .

- Edgar

X
SHAR_EOF
chmod 0600 MX2NET.MOD || echo "restore of MX2NET.MOD fails"
sed 's/^X//' << 'SHAR_EOF' > MX2NOTES.TXT &&
Xnotes.txt
XThese are working notes to help keep track of changes or things that
Xshould or could be done to MX2.
X
X
X#@MX2 file and program directorys
XThere are two new directory that MX2 needs. The first is called \MX2SPOOL
Xthis is created when the spooler program begins for the first time.
XThe second is called \MX2 these should be where all MX2 executable
Xprograms should be. All script file should now look at \MX2 for MX2
Xprograms that they need.
X
X#@mlimit
XNeed a way to limit the amount that any one program can see with a
Xmalloc(-1). I could set up a trap handler to control the malloc but I will
```

```
Xfirst try to allocate small 2 byte memory blocks to break up the memory
Xblock.
X
X#@crashs
XWhen MX2 crashes disk sectors that were being allocated for a file that did
Xnot close can be lost. Use of a program like "TUNEUP" can fix and get back
Xthe "LOST" sectors. Also some auto programs can cause problems with MX2
XI use GEMBOOT.PRG and the mitchtron CACHE.PRG. I have found that the
XL-CACHE.PRG causes lockup and random aborts.
X
X#@xmodem
XNeed to take a look to see why the xmodem routines are messing up later
XI/O with the te command and CLI redirection to the AUX port.
X
X#@menu
XI have started to play with a backgound gem menu bar for the CLI. The
Xprogram MENU sets up a menu bar that can be run in backgound with the
X"sys bp 1 menu" command. The program 'km' will terminate the MENU
Xprogram. Although it works it also totally screws up gem. It's safer run
Xas just a regular program but it you don't care about running another gem
Xprogram try it.
X
X#@WaitProcess MX2V220
XProcedure that waits for a memory location to change it's value.
X   WaitProcess(VAR id: INTEGER; VAR location: ADDRESS; VAR value,mask,msec:
LONGCARD);
XThis procedure puts the currentprocess to sleep then compares the contents
Xat 'location' against 'value AND mask'. If they are the same then the
Xprocess wakes up and is put in the scheduler ready list to be run. msec
Xis the time the process will wait for the value in milliseconds if msec
Xis set to 0 WaitProcess will never timeout.
X** NEED TO ADD TO JSM2 syscall.def
X
X#@submita&submitm
XFixed submita and added submitm to utility programs. I forgot to use the
Xxbios call to get the IOREC for the RS232 buffer.
X
X@#mx2.acc
XIf you want to switch out of a GEM program back to the ALT cli with the
XALT m hotkey you MUST turn off the MX2.ACC first. If you don't the AES
Xwill get very mixed up. When back in the GEM program you can turn the
XMX2.ACC back on to allow normal background program operation. This guy is
Xcauseing some problems I may have to redesign it again.
X
X@#spint control of spooler, network and xmodem
Xspint 0 controls the spooler
Xspint 1 controls both netaux and netmidi
Xspint 2 controls the xmodem send and receive
Xxr = xmodem receive  'xr -crc foo.bar' or 'xr -chk foo.bar'
Xxt = xmodem send     'xt -crc foo.bar' or 'xr -chk foo.bar'
Xxs = xmodem status   'xs'
Xxa = xmodem abort    'xa'
X
```

```
X@#spints
XSpints in MX2 are similar to signals in UNIX. They are procedures that
Xcan be started by issueing a Trigger(x) call. A spint can also carry a
Xmemory location that can be used for shared memory between processes.
XThe source files spooler.mod, sq.mod, lp.mod and killlp.mod are simple
Xexamples.
Xspooler.mod uses the EnableSpint call to setup spint 0 to a procedure
Xsq and a pointer to the variable spintcmd.
Xsq.mod, lp.mod and killlp.mod use the SpintInfo and Trigger calls to
Xcommunicate with the spooler.prg

```
' ------------------------------------------------------------------------
' LIMITER, a Public Domain program by MaDom, <P> 26. Dec. 1988
' Version 1.0 developed in GfA-BASIC 2.0 because the compiler V3 isn't
' available (Oh sh..)
'
' Description:
' If you're using the driver's from Supra or ICD, all drives (A through P)
' are activated. This seems a little stupid, so this program was developed.
' You've to put the program in the folder "AUTO" of your boot device. Then
' you've to rename the program to LIMITERx.PRG, where x means the character
' of your last harddisk partition, eg. LIMITERI.PRG if your last partition
' will be "I:".
'
' CAUTION: The program won't check your inputs, so be careful.
' ------------------------------------------------------------------------
' set dta

Void Gemdos(26,L:Basepage+128)
' &H446 means the boot device, so every boot device will work
Filename$=Chr$(Dpeek(&H446)+65)+":\AUTO\LIMITER?.PRG"+Chr$(0)
' Scan for the name of the program
E%=Gemdos(78,L:Varptr(Filename$),-1)
' Yes, we've got it
If E%=0 Then
  Limit=Peek(Basepage+165)-64
  ' Poke the new number into _drvbits
  Sdpoke &H4C4,(2^Limit)-1
  ' A little bit of Copyright

  Print "LIMITER, a Public Domain program by MaDOM, <P> 26. Dec. 1988"
Endif
End

chmod 0664 makefile || echo "restore of makefile fails"
echo "x - extracting d110.doc (Text)"
sed 's/^X//' << 'SHAR_EOF' > d110.doc &&
XDoc for d110 patch editor:
X
XThe program is full screen, the editing keys are:
X
Xnumeric fields:
X    F1  -16
X    F2  -8
X    F3  -4
X    F4  -2
X    F5  -1
X    F6  +1
X    F7  +2
X    F8  +4
X    F9  +8
X    F10 +10
```

```
X
XAlphanumeric fields:
X    There is no backspace (sorry about the bug)
X    a-z, A-Z, and 0-9 are permitted.
X
XNext and previous fields are the up and down arrow keys.
XLeft and right arrow keys allow moving around inside
Xan alphanumeric field.
X
XWhen the output is directed to the d110 the
Xpatch editor will edit in live mode:  every change
Xwill be reflected immediately.  Messages from a keyboard
Xare copied from the ST's MIDI in and sent the MIDI out
Xwhich allows a keyboard to be used to play the synth
Xwhile making changes to the patch.  Be warned that the d110
Xwill reject patch changes while sounding a tone.  So all
Xnotes on the synth keyboard should be off when making changes
Xon the ST's keyboard.
X
XWhen the output is directed to the d110 the alphabetic keys on
Xthe ST's keyboard form all of the notes in the C arpeggio for
Xall 8 octaves.  The space bar sends an all notes off msg.
XWhile more privitive than having a full keyboard,
Xit allows for live editing without a keyboard.
X
XCabling is difficult, there is no setup that lets you source
Xand sink to the D110 and have a synth keyboard hooked up
Xall at the same time.  You get one or the other but not
Xboth.  To do live editing you need the D110's out connected
Xto the ST's in and the ST's out connected to the D110's in.
X
XFor synth keyboard usage, use the above cabling method first and
Xcopy the patches to disk files.  Then switch cables so that the
Xsynth kbd is connected to the ST's in.  The D110's out will
Xbe disconnected.  When done editing the new patch will be in the
XD110's memory.  Another cable switch and you can copy the new patch
Xto a disk file.
X
XWhat all the patch fields are:
XAll of my names closely track Roland's names.
XIf you have doubts, check the MIDI implementation reference
Xin the back since that is where my names came from.
X
XFile formats:
XMy file formats are exactly the sysex message it would take to
Xsend the data to the d110.  Thus, if your sequencer allows importing
Xsuch files, you can store song setup information in your seqence.
XThe d110 needs about a half a second to digest each such message.
XI did not include a program that would dump sysex files to the
XMIDI port.  Such a program is trivial (for programmers) and I might
Xdo it for those interested.
X
X             - kurt
```

```
X
XOn compiling the source:
X    the memcpy.s file is not referenced in the makefile.
X    It is the only item needed from the archive libar.a
X    (-lar).

sed 's/^X//' << 'SHAR_EOF' > mt32.doc &&
XDoc for MT32 patch editor:
X
XThe program is full screen, the editing keys are:
X
Xnumeric fields:
X    F1  -16
X    F2  -8
X    F3  -4
X    F4  -2
X    F5  -1
X    F6  +1
X    F7  +2
X    F8  +4
X    F9  +8
X    F10 +10
X
XAlphanumeric fields:
```

```
X    There is no backspace (sorry about the bug)
X    a-z, A-Z, and 0-9 are permitted.
X
XMoving from field to field is accomplished with the four
Xarrow keys.
X
XTo exit the current screen hit escape.  To excecute the current
Xscreen and go to a sub-screen hit return.
X
XWhen the output is directed to the mt32 the
Xpatch editor will edit in live mode:  every change
Xwill be reflected immediately.  Messages from a keyboard
Xare copied from the ST's MIDI in and sent the MIDI out
Xwhich allows a keyboard to be used to play the synth
Xwhile making changes to the patch.  Be warned that the mt32
Xwill reject patch changes while sounding a tone.  So all
Xnotes on the synth keyboard should be off when making changes
Xon the ST's keyboard.
X
XWhen the output is directed to the mt32 the second and third
Xrow of keys (q-] and a-') on the ST's keyboard form all of the
Xnotes in the C arpeggio for all 8 octaves.  The space bar sends
Xan all notes off msg.  While more privitive than having a full keyboard,
Xit allows for live editing without a keyboard.
XThe keys 1 through 8 allow one to change velocity
Xsetting on the notes generated from thw ST's keyboard.
X
XCabling is difficult, there is no setup that lets you source
Xand sink to the mt32 and have a synth keyboard hooked up
Xall at the same time.  You get one or the other but not
Xboth.  To do live editing you need the MT-32's out connected
Xto the ST's in and the ST's out connected to the MT-32's in.
X
XFor synth keyboard usage, use the above cabling method first and
Xcopy the patches to disk files.  Then switch cables so that the
Xsynth kbd is connected to the ST's in.  The MT-32's out will
Xbe disconnected.  When done editing the new patch will be in the
Xmt-32's memory.  Another cable switch and you can copy the new patch
Xto a disk file.
X
XWhat all the patch fields are:
XAll of my names closely track Roland's names.
XThe mt32 and the D-50 have similar names for everything.
XI suggest a D-50 book if you can't find an mt32 book at
Xyour local music store.  The D-10/20/110 changed the names
Xfor everything, so while very similar, reading such doc
Xwill be confusing.
X
XAlso, I recommend reading the MIDI implementation in the back
Xfor sysex messages.  This is where I got my names and where you
Xcan find out which kind of memory does what.
X
XFile formats:
```

```
XMy file formats are exactly the sysex message it would take to
Xsend the data to the mt32.  Thus, if your sequencer allows importing
Xsuch files, you can store song setup information in your seqence.
XThe mt-32 needs about a half a second to digest each such message.
XI did not include a program that would dump sysex files to the
XMIDI port.  Such a program is trivial (for programmers) and I might
Xdo it for those interested.
X
X             - kurt
X
XOn compiling the source:
X    the memcpy.s file is not referenced in the makefile.
X    It is the only item needed from the archive libar.a
X    (-lar).
SHAR_EOF
chmod 0444 mt32.doc || echo "restore of mt32.doc fails"
exit 0

Submitted-by: cs.buffalo.edu!sigmast!dgy
Posting-number: Volume 1, Issue 92
Archive-name: starchrt/part01

This archive contains the patches needed to get starchart 2.0 running on the
ST, along with the driver for the ST's color monitor and the utility programs
provided with the companion posting in comp.binaries.atari.st.

#!/bin/sh
# shar:  Shell Archiver  (v1.22)
#
# This is part 1 of a multipart archive
# do not concatenate these parts, unpack them in order with /bin/sh
#
#    Run the following text with /bin/sh to create:
#      Makefile.st
#      README
```

```
#      README.2
#      moonphse.dif
#      planet.dif
#      staranim.c

SHAR_EOF
chmod 0600 Makefile.st || echo "restore of Makefile.st fails"
sed 's/^X//' << 'SHAR_EOF' > README &&
XA hack is used to determine if "moonphse," "planet," "starst," or "staranim"
Xis running from the desktop or the shell.  If the environment variable "PATH"
Xis not set or has a null value, the program assumes it was run from the
Xdesktop and will wait for a keypress before exiting.  If "PATH" is set, it
Xassumes it was run from a shell (since "PATH" is meaningless to the desktop)
Xand will usually exit immediately, the exception being "STARST.TTP" as
Xdescribed in the readme file for the executables.
X
XTwo defines were added to starchart:  ST_MWC defines the Atari ST with the
XMark Williams C compiler, and INTERACTIVE means that the program must reset
Xthe terminal before exiting, so the function die() is located in the driver
Xsource file instead of in starchrt.c for better portability.
X
XReally, very few changes were necessary.  A couple of frustrating bugs turned
Xout to be caused by Mark Williams C's definition of an "int" as 16 bits, which
Xcaused very large numbers to become smaller, negative ones.  Casting them to
X"long" solved the problem, but, as usual, fixing the problem was much easier
Xthan finding it.
X
XNames of programs were changed as follows because of the ST's MS-DOS-like file
Xstructure:
X     moonphase.c --> moonphse.c
X     starchart.c --> starchrt.c
X     starchart.h --> starchrt.h
X     starimages.c --> starimag.c
X     starlaser.c --> starlase.c
X
XBe warned that compiling "planet" requires almost a full megabyte of memory.
XWith my 1040 I had to remove ALL desk accessories and AUTO folder programs,
Xand even then had to redirect the output of "make -n planet.ttp" into a file
Xand invoke it as a shell script, due to the overhead of running "make."
X
XSee the file "readme.2" for the readme files that were included with the
Xoriginal distributions.
X
XObligatory Caveat:  I make no guarantees as to the robustness or accuracy of
Xthis port of starchart.  While I am sure there are no devestating bugs in it,
Xshould one appear I am not responsible for any damage or misinformation it
Xmay cause.
X
XAll programs were compiled with Mark Williams C, version 3.0.6; portions of
Xthese programs copyright 1984, Mark Williams Company.
X
Xquestions or comments on the ST version only should go to:
```

```

XREADME1 ========================================================================
X
XSTARCHART (rev 2)
X-------------------------------------------------------------------------------
XNote: This version is upward compatable with the original "starchart" software
Xfamily, both in user interface and in continued support of the original
Xreduced Yale catalog. Thus, it may supplant old copies of the software without
Xfear that either shell scripts or file formats will become invalid.
X
XHowever, both the new user interface and the extended catalog are
Xsuperior, as are extensions for additional labelling (Greek characters,
Xdouble star indicators, Messier objects), plus a mnemonic "finder" facility.
X-------------------------------------------------------------------------------
X
XINSTALLATION INSTRUCTIONS:
X
X[1]
XSave the new posting of the reduced Yale Star Catalog under the name
X"yale.star" (or use a copy of the old version). If the save directory is other
Xthan the one in which the program lives, then check out the Makefile, which
Xallows path names to be specified for compilation.
X
XSites without much disk space may truncate the file yale.star at any point,
Xas the data is sorted in order of increasing magnitude (dimming).
X
XAdditonally, the optional files "messier.star" and "con.locs" should be
Xplaced in the chosen directory. Entries in these files are unsorted. The
Xoptional file "planet.star" is created on an as-needed basis by the softwaare
X"planet.c", and might want a home in some less permanent (writable) location.
X
X[2]
XDo a "make all" to compile all software. They are described in the man pages
X"starchart.1" and "planet.1" . All compile using starchart.c as the mainline,
Xwith device driver specifics in modules of appropriate name.
X
X[3]
XYou may now try "man test" to make an Orion pic file similar to the one
Xposted to the net. Or you may test by outputting to the tty display, using the
Xversion "stardsp". This is described in the EXAMPLE section of the man page.
X
XVERSION NOTES:
X
XTty display users (*sigh*) may which to alter "stardsp" to output
Xto the display using an appropriate number of of rows and columns
Xon the screen. (Presently 31x79 for a 32x80 display. 23x79 is a
Xbit sparse).  Find the ROWS and COLS #defines in stardsp.c
Xand update. Or be really ambitious and recode them as run time
Xvariables.
X
```

XTektronix emulator users may wish to alter scaling parameters based on the
Xactual physical dimensions of the display raster, to get the cleanest possible
Xstar glyphs on output. This is described at length in the beginning of the
Xdriver "startek.c".
X
XPic file users: the #define PICFRAG can be adjusted downward
X(presently 8) should your pic input overflow pic's buffers. This
Xhappens when a long move,draw,draw,...,draw sequence happens.
XSmaller PICFRAGs make larger files, by forming fragmented
Xmove,draw commands.
X
XPostScript users: you may wish to play with the boiler-plate macros which
Xdefine star shapes (e.g. 's1' does first magnitude stars). This is mentioned
Xat the end of starchart.c
X
XLaserjet users: the output of starlaser must be directed to
Xlaserjet via raw connection, because it is largely sent in binary
X8-bit format. The graphics memory might overflow if you use the
Xstandard (oldest) 59k buffer laserjet (*sigh*). Anyway, I haven't
Xever lost any relevant data on the sheet: the overflow has occurred on
Xthe last few blank pixel rows of the graphics area. If you use
Xlaserjet plus, you shouldn't have any problems.
X
XOther devices: don't expect the authors to write a new driver for you :-)
XLook through the sources - it's not so difficult after all... The module
X"starimages.c" provides support for bitmap devices; the PostScript driver
Xis a good example of generating output in some graphics language.
X
XMore ambitious programmers may wish to extend the usefulness of these programs.
XBe our guest, but carefully consider the proposed list of suggestions which
Xintentionally accompanies the main source code body "starchart.c". It is hoped
Xthat future changes and major revisions and their subsequent integration will
Xbe kept relatively simple by coordinating efforts and by not duplicating work.
X
Xawpaeth@watcgl (original author and revisions editor)
Xinp@amber.berkeley.EDU (revisionist for user interface)
Xpl@sibelius.intrin.FI (support for mini-Yale, Messier and finder catalogs)
X
XREADME2 ==
X
X[from awpaeth:]
XThis is the SOFTWARE update kit for StarChart version #2
Xwhich was released in Nov/Dec 1987. The kit performs an upgrade to ver #2.1
XNo upgrades to yale.star or other .star files occurs.
X
XThis kit updates StarChart version #2 software as it appeared in that release -
Xno other patches should already be in place. Virgin copies of version #2 are
Xavailable from the moderator of comp.sources.unix.
X
X
XOverview of Changes
X
XMore portability across sysV and IRIS UNIX installations.

```
XA particularly nasty bug in planet.c was removed.
XTwo new device drivers were added (Unix Plot(5) and Iris).
XStarChart now performs full clipping of vectors.
XAdditional flags for creating stylized output and larger displays.
XPostScript now has nicer symbols for non-stellar objects.
XMore detailed patch and upgrade notes appear in the source code.
X
XFILES
X
XName              Description/Instructions
X----              ------------------------
XREADME             this file
Xpatch-*            patches for moonphase.c, planet.c, drivers, yaleformat
Xpatchall      runs the above patches on the originals
Xstarchart.1        new man page
Xstarchart.c        rewritten main driver (easier to reinstall then patch)
Xstarchart.h        accompanying new .h file for above (ditto)
Xstariris.c         new IRIS driver
Xstaruplot.c        new UNIX Plot(5) driver
X
XREADME3 ========================================================================
X
XOver the last few weeks I have generated a database of constellation
Xboundaries.  This database does NOT include the constellation figures, just
Xthe boundaries defining the area of the sky the constellation contains.
XThis database is in the 'old starchart' format, thus it will work for the
Xrecently posted starchart version 2.0 and the original starchart 1.0.
X
XThis data was hand compiled from the Sky_Atlas_2000.0.  Each constellation
Xhas it's entire boundary defined, thus each adjacent constellation will define
Xthe same vector (it will exist twice in the database).
X
XTo make this work for the starchart program, a modification is needed in the
X'chartobjects' procedure.  I have included the entire procedure in the
Xshar file following this message.  The only changes were at the top where
XI added some simple window clipping checks for the vectors and a couple
Xof new variables.  Any vector outside the defined window will be converted
Xto a 'move' command and placed at the window edge.  You can either replace
Xthe entire procedure or just make the necessary changes.
X
XIf you wish the boundaries to always be charted, you should modify the
Xstarchart.c module to read in and chart the boundary.star file just like
Xthe other databases.  If you only rarely chart them, then just use the
X'-f' option in starchart version 2.0
X
XHave fun.
XDave

Archive-name: passm/part01

[Documentation is the first part of the sharfile, so page down a bit to read
 it. This program probably isn't for everyone. Binaries will appear in the
 binaries group. -sg]

```
#!/bin/sh
# shar:  Shell Archiver  (v1.22)
#
# This is part 1 of a multipart archive
# do not concatenate these parts, unpack them in order with /bin/sh
#
#    Run the following text with /bin/sh to create:
#      passm.doc
#      PASSM.PAS
#
if test -r s2_seq_.tmp
then echo "Must unpack archives in sequence!"
     next=`cat s2_seq_.tmp`; echo "Please unpack part $next next"
     exit 1; fi
sed 's/^X//' << 'SHAR_EOF' > passm.doc &&

X
X
X
X
X
X
X     _I_n_t_r_o_d_u_c_t_i_o_n
X
X             Passm, a PAL Assembler,  allows  the  user  to  write  boolean
X     equations  describing  the outputs of a PAL and generates a JEDEC fuse
```

X file. This assembler supports most 20 and 24 pin PALs. Currently, the
X list of parts supported are:
X
X
X

```
>module< module_name{;}   {optional_sections}
  device_type_declaration
  pin_list_section
  boolean_equations
>end<
```

The module_name is an identifier, no more than 15 characters, which must start with a letter. The set of valid characters for an identifier is : a..z, A..Z, underscore '_', and the minus sign '-'. Notice that the semicolon ending the module name is optional.

The next element within a module is the optional_section. This section is being reserved for future features, such as flags indicating what type of reduction to do with the boolean equations, include files, etc. At the present time, no optional features are enabled.

The next section is the device_type_declaration. This section informs PASSM as to what type of device is being targeted, ie. a 16r4, etc. This section syntax is as follows:

```
device_name  >device<  >'<part_type>';<
```

The device_name, an identifier, is the symbolic name with which the user may refer to the PAL. The part_type is the actual device being programmed. The following is the list of available devices:

20 Pin Pals	24 Pin Pals
p10l8, p10h8	p12l10
p12l6, p12h6	p14l8
p14l4, p14h4	p16l6
p16l2, p16h2	p18l4
p16l8	p20l2
p16r4	p20l10
p16r6	p20l8
p16r8	p20r4
	p20r6
	p20r8
	p22v10

```
X
X     Notice that the part_type must appear as shown above.
X
X             The next section in a module description is the pin list. This
X     section provides a symbolic reference between the signal names used in
X     the equations, and the device physical pins. The syntax followed is:
X
X
X          signal_name {, signal_name}  >pin< pin_numbers >;<

X *
X * NAME
X *    life   - the game of life (graphics demo if you want)
X *
X * SYNTAX
X *    life.ttp [-d|-D] [-w wait] [01-pattern ...]
X *
X * DESCRIPTION
X *    This program barely needs comments. 'Generations' are created on a grid,
X *    on a step by step basis. The criterium used for a cell to survive
X *    (resp. die), is that it has between BOT (3) and TOP (4) neighbours
X *    (resp. has not).
X *
X *    The program runs only in high and medium resolution modes (so everyone
X *    should be able to run it); not supporting low res is entirely due to
X *    laziness on my part 8-), but since no colours are involved (yet) it
X *    seemed an unnecessary addition.
X *
X *    For both resolutions supported you can choose a coarse grid (25 x 40)
X *    and a fine one (50 x 80); default is coarse, and the -d or -D (double)
X *    option selects the fine grid.
X *
X *    The -w or -W option lets you specify an amount of time to wait between
X *    generations (default is nowait).
X *
X *    Any remaining arguments are taken to be the initial patterns to be placed
X *    on the grid, a '0' representing an empty cell, a '1' a filled one. These
X *    patterns are placed on subsequent rows, near the middle of the screen.
X *    Some pattern sets generate repetitive populations, other die away, still
X *    other generate nice ever-changing patterns. Experiment. Symmetric sets
X *    are (possibly) favorite; this means using symmetric patterns, with the
X *    first matching the last, the second the last but one, etc., and using an
X *    odd number of patterns in the coarse grid case and an even number of
X *    patterns in the fine grid case. You could alternative use point symmetry
X *    instead of line symmetry; figure out for yourself how to arrange this.
X *    If there are no remaining arguments after any flags, a random pattern is
X *    generated.
X *
X *    To finish the game, 'press any key ...'
X *
X * EXAMPLE
X *    life -d -w 20 011110 110011 101101 001100 101101 110011 011110
X *
X *    will have a fine grid, a wait pause of 20, and an initial pattern set
X *    that looks like:
X *                                  ****
X *                                **  **
X *                                * ** *
X *                                  **
X *                                * ** *
X *                                **  **

X * DECISIONS
```

```
X *    Screen access is done directly, for speed reasons (we must be able to
X *    print several hundreds of characters, several times per second, if we
X *    want screen updates to appear - almost - immediate).
X *    On the other hand, C proved to be quite fast enough, so there was no
X *    need to resort to assembler.
X *    Each resolution and each mode (coarse/fine) demands it own treatment,
X *    so four separate (functional identical) functions were written, one
X *    for each of them.
X *
X *    By using a private startup routine (not included) instead of the
X *    compiler supplied one, the size of the program could be kept
X *    considerably smaller (not using stdio).

Submitted-by: John.Altstadt@moliman.molienergy.bc.ca (John Altstadt)
Posting-number: Volume 2, Issue 13
Archive-name: shar

[I know, this is like posting a uuencoded binary for "uudecode", but... -sg]

Here is a somewhat updated version of shar (including unshar) that was
posted to the net many years ago.  I have included the original readme
file (complete with typo's) plus many typo's of my own.  If somebody
wants to clean up the code, or add more features, be my guest.  Binaries
have been sent to the binaries group.

#    This is a shell archive.
#    Remove everything above and including the cut line.
#    Then run the rest of the file through sh.
#----cut here-----cut here-----cut here-----cut here----#
#!/bin/sh
# shar:  Shell Archiver
#    Run the following text with /bin/sh to create:
#    readme
#    makefile
#    shar.c
# This archive created: 31-January-1989 20:09:20 ENOENV
```

```
# By:     ENOENV (ENOENV)
echo shar: extracting readme
sed 's/^X//' << \SHAR_EOF > readme
X
XThe next two files make up a shar/unshare program for the ST and vax VMS.  I
Xhave tested both versions and they work the same on each system.  I've had
Xthis source for quite a while and have been using it on VMS, but hadn't
Xbothered to port it to the ST until recently.  The first file is the shar
Xarchive for source and the link68 linkfile.  The second file is the uuencoded
Xbinary shar.prg.  I haven't prefixed the lines so that you can easily
Xextract the files without the progrm itself.  The original was posted to
Xnet.sources last year.  This one has had some bugs removed and most of the
Xamiga/cpm stuff deleted (it made it difficult to decipher the code).  But I
Xleft the VMS conditionals in place to make it easy to get versions running
Xon the two machines.  Hope you can find a use for this.  I sure have.
X
SHAR_EOF
if test 819 -ne "`wc -c readme`"
then
echo shar: error transmitting readme '(should have been 819 characters)'
fi
echo shar: extracting makefile
sed 's/^X//' << \SHAR_EOF > makefile
XCFLAGS  = -A -VSMALL
X
Xshar.ttp : shar.c makefile
X    cc shar.c $(CFLAGS) -o shar.ttp
X    strip shar.ttp
SHAR_EOF
if test 97 -ne "`wc -c makefile`"
then
echo shar: error transmitting makefile '(should have been 97 characters)'
fi
echo shar: extracting shar.c
sed 's/^X//' << \SHAR_EOF > shar.c
X/*
X *  Shar puts readable text files together in a package
X *  from which they are easy to extract.
X *
X *  v 860716 M. Kersenbrock (tektronix!copper!michaelk) for Z80-CPM
X *  - enhanced usage message
X *
X *  v 860712 D. Wecker for ULTRIX and the AMIGA
X *  - stripped down.. does patterns but no directories
X *  - added a -u (unshar) switch
X *
X *  v 870128 R. Royar for ST
X *  - removed #ifdefs that left stray }s in file
X *  - reformatted text for consistant style
X *  - modified main to abort when no files are given
X *  - fixed call to fputc in tell macro, which omitted the stream
X *    causing address errors on the ST.
X *  - fixed STUPID coding in getopt that tried to write to
```

```
X *    address 0++.
X *  - known bugs:
X *       still no directory support.  Extracting
X *       files with directory names will get
X *       only the directory name on an open call.
X *
X *  v 880713 J. Altstadt for ST
X *  - removed extraneous #ifdefs for all other systems
X *  - reformatted text for consistant style
X *  - changed lots of things for unsharing:
X *    1. added directory handling
X *    2. added code to handle weird shar sed formats better,
X *       will add more things when i get files that i can't unshar,
X *       eg. when i get one of those icky sharchives that has split files
X *       but won't add in the ability to handle shars that use awk to
X *       extract files (yes, windsrch uses awk, blech!!!)
X *    3. added in file overwrite protection, i didn't need it, but it was
X *       easy (and i know i will need it some day when i don't have a
X *       backup)
X *    4. skip whitespace at begining of lines intended for sh, so it will
X *       do stuff embedded in "if test" structures
X *
X *  v 890124 J. Altstadt for ST
X *  - unshar will handle files split across two (or more) sharchives
X *  - fixed bug that would allow creation of directories (files) with
X *    the same name as an existing file (directory)

Submitted-by: uunet!mcvax!cwi.nl!eddy (Eddy Boeve)
Posting-number: Volume 2, Issue 14
Archive-name: keyfix

Here is a program to fix the 'gulam.prg' binary for non-american keyboards.
You do not have to edit the program, just run it. The program does the
rest. The binary is also being posted in comp.binaries.atari.st.

```
/*
 *   keyfix.c -- Utility for Gulam
 *
 *   Original version: copyright (c) 1986, 1987 pm@cwru.edu
 *
 *   Rewrite  : eddyright (e) 1989 eddy@cwi.nl
 *
 *   This is an utility for GULAM to patch the default key bindings
 *   in the 'gulam.prg' binary. It was originally created by
 *   'pm@cwru.edu' to change the USA key bindings for us Europeans
 *   and contained a 3*128 table with the desired new bindings.
 *
 *   This version is different because you don't have to edit it for
 *   your own machine. It works out for itself what keys produce what
 *   characters.
 *
 *   This program takes your default key translation tables via the
 *   XBIOS function 'Keytbl' and adds the GULAM function, arrow and
 *   keypad key translations. (Why Gulam doesn't do this is unclear).
 *   If you already have a USA key binding, everything will stay the
 *   same. Otherwise the '@~#\|$' keys will hopefully appear under the
 *   right button.
 *
 *   Compile 'kmpfix.c'.  Run the resulting program from the directory
 *   that contains the 'gulam.prg'.
 *   The new version of 'gulam.prg' (with the new key mapping) will be
 *   written out as 'gulamnew.prg' in the current directory.
 *
 *   Below we define ST520/1040 keynames; the values are the ascii codes
 *   returned by ST BIOS.
 *
 *   The values below are chosen to have certain patterns:
 *
 *   to SHIFT   add 0040
 *   F1-10           0201 to 0212
 *   keypad 0-9      0260 to 0272 (subtract -0200 to get ascii digits)
 *   keypad()/ *-+.cr  add 0300 to the ascii ()/ *-+.cr
 *
 *   Other choices may be better, I don't know.  However, I think it is
 *   unwise to use numbers in the range 0000 to 0177, because they are
 *   regular ascii codes.
 *
 *   If you want to change some bindings, do it in the routine
 *   'copy_map':
```

```
 *       kn['scan_code'] = 'ascii_code';
 *
 *   Exit values:
 *        0   : No errors,
 *       -1   : Error in finding key map in binary,
 *       -2   : Error in memory allocation,
 *       -3   : Error in file reading/writing.
 */

Submitted-by: saj@chinet.chi.il.us (Stephen Jacobs)
Posting-number: Volume 2, Issue 15
Archive-name: sed/part01

This is the first of 2 parts of source/text and one part of binary of sed
working on the Atari ST.  The executable was compiled with Mark Williams
C, v3.06.  Due to the limitations on distribution mentioned in sed.man,
I think sed.man should not be arc-ed together with the executable, but should
only be part of the source distribution.  [That's what I've done. -sg]

It is an implementation of the Unix utility of the same name, and that even
though it's named sed.ttp it really shouldn't be run from the desktop
because the input is case sensitive.

#! /bin/sh
```

```
# This is a shell archive.  Remove anything before this line, then unpack
# it by saving it into a file and typing "sh file".  To overwrite existing
# files, type "sh file -c".  You can also feed this as standard input via
# unshar, or by typing "sh <file", e.g..  If this archive is complete, you
# will see the following message at the end:
#        "End of shell archive."

XAfter putting an unreasonable amount of effort into debugging this beast, I
Xfeel entitled to add a few words to what's already in the .man file.
X
```

```
XThe main reason I wanted sed was to help distinguish defining and referencing
Xdeclarations of external variables in C.  Andy Tanenbaum got me started on
Xthis in his Operating Systems, Design and Implementation (the MINIX book).
XAnyway, I adopted his idea of a pre-processor macro that expands to a
Xgramatically proper referencing declaration everywhere except in one file,
Xwhere it is redefined to expand to a proper defining declaration.  This does
Xnot serve for initialized external variables, however.  My solution follows:
X
XThe macros EXTERN add Initialize are defined as
X
X#define EXTERN extern
X#define INITIALIZE(type, name, value) extern type name
X
Xexcept in one file, which says
X
X#undef EXTERN
X#undef INITIALIZE
X#define EXTERN
X#define INITIALIZE(type, name, value) type name = (value)
X
XThis allows things like
X
XINITIALIZE(double, imagintvl, -.0125);
XEXTERN double reintmp, imintmp;
XEXTERN struct complex upleft, center;
XINITIALIZE(int, drawarray[4], ({0, 9, 0, 0}));
X
XFine so far.  But that initializer {0. 9, 0, 0} really does need to be
Xenclosed in parentheses, because only parentheses can protect a comma from
Xbeing taken as a token delimiter by the C pre-processor.  Similarly,
Xthe INITIALIZE macro really should put the initializer in parentheses
Xto avoid unpleasant surprises.  Imagine my surprise when C compilers
Xrejected "int drawarray[4] = (({0, 9, 0, 0}));".  It seems that the syntax
Xof a multi-value initializer requires " = <optional whitespace> {".  Damn.
X
XSed to the rescue!! My makefile for a complex program now includes
X
X
Xexpanded.c:  defines.c
X    cc -E defines.c > $(TMPDIR)\expanded
X    sed -e '/=/s/(\([{"].*\));/\1;/' $(TMPDIR)\expanded > $(TMPDIR)\filtered
X    sed -e '/=/s/(\([{"].*\));/\1;/' $(TMPDIR)\filtered > expanded.c
X
XTa daaa!
X                  Stephen Jacobs (saj@chinet.chi.il.us)

XNAME
X   sed - the stream editor
X
X
XSYNOPSIS
X   sed [-n] [-g] [-e script ] [-f sfile ] [ file ] ...
X
X
XDESCRIPTION
X   Sed copies the named files (standard input default) to the standard
Xoutput, edited according to a script of commands.
X   An -e option supplies a single edit command from the next argument;
Xif there are several of these they are executed in the order in  which
Xthey appear. If there is just one -e option and no -f 's, the -e  flag
Xmay be omitted.
X   An -f option causes commands to be taken from the file "sfile";  if
Xthere are several  of these they are  executed in the order  in  which
```

Xthey appear; -e and -f commands may be mixed.
X   The -g option causes sed to act as though every substitute command
Xin the script has a g suffix.
X   The -n option suppresses the default output.
X
X   A script consists of commands, one per line, of the following form:
X
X[address [, address]] function [arguments]
X
X   Normally sed cyclically copies a line of input into a current text
Xbuffer, then applies all commands whose addresses select the buffer in
Xsequence, then copies the buffer to standard output and clears it.
X   The -n option suppresses normal output (so that only p and w output
Xis done). Also, some commands (n, N) do their own line reads, and some
Xothers (d, D) cause all commands following in the script to be skipped
X(the D command also suppresses the clearing of the current text buffer
Xthat would normally occur before the next cycle).
X
X   It is also helpful to know that there's a second buffer (called the
X'hold space' that can be copied or appended to or from or swapped with
Xthe current text buffer.
X
X   An address is: a decimal numeral (which matches the line it numbers
Xwhere line numbers start at 1 and run cumulatively across files), or a
X`$' that addresses the last line of input, or a context address, which
Xis a `/regular expression/', in the style of ed (1) modified thus:
X
X(1) The escape sequence `\n' matches a newline embedded in the buffer,
X   and `\t' matches a tab.
X
X(2) A command line with no addresses selects every buffer.
X
X(3) A command line with one address selects every buffer that matches
X   that address.
X
X(4) A command line with two addresses selects the inclusive range from
X   the first input buffer that matches the first address through the
X   next input buffer that matches the second. (If the second address
X   is a number less than or equal to the line number first selected,
X   only one line is selected.) Once the second address is matched sed
X   starts looking for the first one again; thus, any number of these
X   ranges will be matched.
X
X   The negation operator '!' can prefix a command to apply it to every
Xline not selected by the address(es).
X
X   In the following list of functions, the maximum number of addresses
Xpermitted for each function is indicated in parentheses.
X   An argument denoted "text" consists of one or more lines, with all
Xbut the last ending with `\' to hide the newline.
X   Backslashes in text are treated like backslashes in the replacement
Xstring of an `s' command and may be used to protect initial whitespace
X(blanks and tabs) against the stripping that is done on every line of

Xthe script.
X
X   An argument denoted "rfile" or "wfile" must be last on the command
Xline. Each wfile is created before processing begins. There can be at
Xmost 10 distinct wfile arguments.
X
Xa "text"   (1)
X   Append. Place text on output before reading the next input line.
X
Xb "label" (2)
X   Branch to the `:' command bearing the label. If no label is given,
Xbranch to the end of the script.
X
Xc "text"   (2)
X   Change. Delete the current text buffer. With 0 or 1 address, or at
Xthe end of a 2-address range, place text on the output. Start the next
Xcycle.
X
Xd   (2)
X   Delete the current text buffer. Start the next cycle.
X
XD   (2)
X   Delete the first line of the current text buffer (all chars up to the
Xfirst newline). Start the next cycle.
X
Xg   (2)
X   Replace the contents of the current text buffer with the contents of
Xthe hold space.
X
XG   (2)
X   Append the contents of the hold space to the current text buffer.
X
Xh   (2)
X   Copy the current text buffer into the hold space.
X
XH   (2)
X   Append a copy of the current text buffer to the hold space.
X
Xi "text"   (1)
X   Insert. Place text on the standard output.
X
Xl   (2)
X   List. Sends the pattern space to standard output. A "w" option may
Xfollow as in the s command below. Non-printable characters expand to:
X   \b -- backspace (ASCII 08)
X   \t -- tab   (ASCII 09)
X   \n -- newline   (ASCII 10)
X   \r -- return   (ASCII 13)
X   \e -- escape   (ASCII 27)
X   \xx -- the ASCII character corresponding to 2 hex digits xx.
X
Xn   (2)
X   Copy the current text buffer to standard output. Read the next line

Xof input into it.
X
XN   (2)
X   Append the next line of input to the current text buffer, inserting
Xan embedded newline between the two. The current line number changes.
X
Xp   (2)
X   Print. Copy the current text buffer to the standard output.
X
XP   (2)
X   Copy the first line of the current text buffer (all chars up to the
Xfirst newline) to standard output.
X
Xq   (1)
X   Quit. Branch to the end of the script. Do not start a new cycle.
X
Xr "rfile" (1)
X   Read the contents of rfile. Place them on the output before reading
Xthe next input line.
X
Xs /regular expression/replacement/flags   (2)
X   Substitute the replacement for instances of the regular expression
Xin the current text buffer. Any character may be used instead of `/'.
XFor a fuller description see ed (1).
X   Flags is zero or more of the following:
X
Xg -- Global. Substitute for all nonoverlapping instances of the string
X   rather than just thefirst one.
X
Xp -- Print the pattern space if a replacement was made.
X
Xw -- Write. Append the current text buffer to a file argument as in a
X   w command if a replacement is made. Standard output is used if no
X   file argument is given
X
Xt "label" (2)
X   Branch-if-test. Branch to the : command with the given label if any
Xsubstitutes have been made since the most recent read of an input line
Xor execution of a `t'or `T'. If no label is given, branch to the end
Xof the script.
X
XT "label" (2)
X   Branch-on-error. Branch to the : command with the given label if no
Xsubstitutes have succeeded since the last input line or t or T command.
XBranch to the end of the script if no label is given.
X
Xw "wfile" (2)
X   Write. Append the current text buffer to wfile .
X
XW "wfile" (2)
X   Write first line. Append first line of the current text buffer
Xto wfile.
X

Xx   (2)
X   Exchange the contents of the current text buffer and hold space.
X
Xy /string1/string2/   (2)
X   Translate. Replace each occurrence of a character in string1 with
Xthe corresponding character in string2. The lengths of these strings
Xmust be equal.
X
X! "command"   (2)
X   All-but. Apply the function (or group, if function is `{') only to
Xlines not selected by the address(es).
X
X: "label" (0)
X   This command does nothing but hold a label for `b' and `t' commands
Xto branch to.
X
X=   (1)
X   Place the current line number on the standard output as a line.
X
X{   (2)
X   Execute the following commands through a matching `}' only when the
Xcurrent line matches the address or address range given.
X
X   An empty command is ignored.
X
X
XPORTABILITY
X   This tool was reverse-engineered from BSD 4.1 UNIX sed, and (as far
Xas the author's knowledge and tests can determine) is compatible with
Xit. All documented features of BSD 4.1 sed are supported.
X
X   One undocumented feature (a leading 'n' in the first comment having
Xthe same effect as an -n command-line option) has been omitted.
X
XThe following bugs and limitations have been fixed:
X   * There is no hidden length limit (40 in BSD sed) on w file names.
X   * There is no limit (8 in BSD sed) on the length of labels.
X   * The exchange command now works for long pattern and hold spaces.
X
XThe following enhancements to existing commands have been made:
X   * a, i commands don't insist on a leading backslash-\n in the text.
X   * r, w commands don't insist on whitespace before the filename.
X   * The g, p and P options on s commands may be given in any order.
X
XSome enhancements to regular-expression syntax have been made:
X   * \t is recognized in REs (and elswhere) as an escape for tab.
X   * In an RE, + calls for 1..n repeats of the previous pattern.
X
XThe following are completely new features:
X   * The l command (list, undocumented and weaker in BSD)
X   * The W command (write first line of pattern space to file).
X   * The T command (branch on last substitute failed).
X   * Trailing comments are now allowed on command lines.

```
X
X   In addition,  sed's error messages have been made more specific and
Xinformative.
X
X   The implementation is also  significantly  smaller and  faster than
XBSD 4.1 sed. It uses only the standard I/O library and exit.
X
X

X/* sedcomp.c -- stream editor main and compilation phase
X
X   The stream editor compiles its command input  (from files or -e options)
Xinto an internal form using compile() then executes the compiled form using
Xexecute(). Main() just initializes data structures, interprets command line
Xoptions, and calls compile() and execute() in appropriate sequence.
X   The data structure produced by compile() is an array of compiled-command
Xstructures (type sedcmd).  These contain several pointers into pool[], the
Xregular-expression and text-data pool, plus a command code and g & p flags.
XIn the special case that the command is a label the struct  will hold a ptr
Xinto the labels array labels[] during most of the compile,  until resolve()
Xresolves references at the end.
X   The operation of execute() is described in its source module.

Xsedexec.c -- execute compiled form of stream editor commands
X
X   The single entry point of this module is the function execute(). It
Xmay take a string argument (the name of a file to be used as text)  or
Xthe argument NULL which tells it to filter standard input. It executes
Xthe compiled commands in cmds[] on each line in turn.
X   The function command() does most of the work. Match() and advance()
Xare used for matching text against precompiled regular expressions and
Xdosub() does right-hand-side substitution.  Getline() does text input;
Xreadout() and memcmp() are output and string-comparison utilities.

Archive-name: sort/part01

This sort program will appear familiar to *nix freaks. You can use it
to sort and/or merge multiple input files on several keys (numeric,
lexicographic). All hardware configurations should be supported (at
least I don't think it is dependent on resolution, memory size, disk
type etc.). Binary & docs submitted to comp.binaries.atari.st.

```
#!/bin/sh
# shar:  Shell Archiver  (v1.22)
#
# This is part 1 of a multipart archive
# do not concatenate these parts, unpack them in order with /bin/sh
#
#    Run the following text with /bin/sh to create:
#      fastcmp.asm
#      readme
#      sort.c
#      sort.doc
#      sortcomp.c
#      sortcomp.h
#      sortfile.c
#      sortfile.h
#      sortmain.c
#      sortmain.h
#
if test -r s2_seq_.tmp
then echo "Must unpack archives in sequence!"
     next=`cat s2_seq_.tmp`; echo "Please unpack part $next next"
     exit 1; fi
sed 's/^X//' << 'SHAR_EOF' > fastcmp.asm &&

X*****************************************************************************
X*
X* fastcmp.asm: fast sort functions
X*
X*   The code here presented is offered as a replacement for some of the C
X*   functions present in sortcomp.c. Since comparisions are done a lot while
X*   sorting, some performance tweaking didn't seem misplaced.
X*
X*   As for documentation, a reference is made to the corresponding C functions
X*   in sortcomp.c. Most of the code here does simple work, like swapping
X*   arguments (for the 'r' options), and/or skipping white space (for the 'b'
X*   options; marked by 'skips' labels).

X
X                               Sort
X                               ----
X
X
X   The sort utility here presented is comparable to the Unix sort utility;
X   even most of the flags are the same. Sorting is done in core as much as
X   possible; else a \tmp directory (or a user supplied one) is used for
X   creation of temporary files.
X
X   Two speedups have been done that might affect portability:
X       1) a sortfile.c module is added that is included if the symbol BESTIO
X   is defined. The stdio buffers have been increased to 2K, which seems a
X   better choice than the standard 512.
X       2) a fastcmp.asm module is added for faster comparision functions;
X   these functions are taken from sortcomp.c if M68000 is not defined.
X
X   Contents of complete package:
X
X      fastcmp.asm    - module containing faster comparision functions
X      readme         - this introductory file
X      sort.c         - module containing basic sort functions
X      sort.doc       - manual page for sort
X      sort.prg       - the executable program
X      sortcomp.c     - module containing comparision functions
X      sortcomp.h     - header for sortcomp module
X      sortfile.c     - module containing improved I/O functions
X      sortfile.h     - header for sortfile module
X      sortmain.c     - main module; argument scanning; general key matching
X      sortmain.h     - header for sortmain module
X
X   It will probably be distributed in two chucks: one containing .c and .h
X   files, readme and sort.doc (submitted to comp.sources.atari.st) and one
X   containing sort.prg, readme and sort.doc (s. to comp.binaries.atari.st).
X
X   Compiled with Lattice C; first compiler pass with -dBESTIO option, second
X   with -r option. Fastcmp.asm was assembled using the GST linker.
```

```
X
X   This program was the result of a question on the net, asking for a disk
X   based sort. It seemed like a nice project (in fact, it was 8-), and I
X   hope at least the person who asked it can make some use of it.
X
X   For questions, bug reports etc. try

X
X
XNAME
X     sort - sort and/or merge files
X
XSYNTAX
X     sort [ -bdfimnrutx ] [ +pos1  [ -pos2 ] ] [ -o name ] [ -T dir ] [ name...]
X
XDESCRIPTION
X     Sort sorts, then writes the lines of the named files to its standard
X     output, or a file (-o option).
X     Default (no input files are named), the standard input is sorted.
X     The name "-" stands for the standard input, so that standard input can be
X     used together with other input files.
X
X     By default, the sort key is an entire line; ordering is lexicographic.
X     The global ordering is affected by zero or more of the following options
X     (of which some combinations are meaningless, e.g. d and n).
X
```

```
X     -b   Leading blanks (spaces and tabs) are skipped in field comparisons.
X
X     -d   Dictionary order: only letters, digits and blanks are
X          significant in comparisons.
X
X     -f   Fold: treat upper case as if lower case.
X
X     -i   Ignore characters outside the ASCII range 040-0176 in
X          nonnumeric comparisons.
X
X     -n   An initial numeric string, consisting of optional
X          blanks, optional minus sign, and zero or more digits
X          with optional decimal point, is sorted by arithmetic
X          value. This option implies option b.
X
X     -r   Reverse the result of comparisons.
X
X     -tx  `Tab character' field separator is x.
X
X     The notation +pos1 -pos2 restricts a sort key to a field
X     beginning at pos1 and ending just before pos2.
X     Pos1 and pos2 each have the form m.n, optionally followed by one
X     or more of the options bdfinr, where m tells a number of fields
X     to skip from the beginning of the line and n tells a number
X     of characters to skip further.  If any options are present
X     they override all the global ordering options for this key.
X     If the b option is in effect n is counted from the first
X     nonblank in the field.
X     A missing .n means .0; a missing -pos2 means the end of the
X     line.  Under the -tx option, fields are strings separated by
X     x; otherwise fields are nonempty nonblank strings separated
X     by blanks.
X
X     When there are multiple sort keys, later keys are compared
X     only after all earlier keys compare equal.
X
X     These are additional (global) options:
X
X     -c   Check that the input file is sorted according to the key(s);
X          if the file is out of sort, an error message is printed.
X          Exit code is 0/1 for correctly/incorrectly sorted input.
X
X     -m   Merge only, the input files are already sorted.
X
X     -o   The next argument is the output file used instead of the
X          standard output. This file may be the same as one of the inputs.
X
X     -T   Temporary files directory. Default is \tmp on the current drive.
X
X     -u   Unique: Select only one in each set of, according to the
X          key(s), equal lines.
X
XRESTRICTIONS
```

```
X     Very long (>256 chars) lines are silently truncated.
X     The line terminator sequence \r\n is present in the line when
X     doing comparisions; this should not present problems. Use of \0 in
X     input is discouraged, since this will be seen as a C string terminator.
X
XDIAGNOSTICS
X     Comments and exits with nonzero status for various trouble
X     conditions and for disorder discovered under option c(heck).
X
XFILES
X     \tmp\*  for temporary files.
X

X/*****************************************************************************
X *                                                                           *
X *   sortcomp.c  version 1.0 of  1 Januari 1989    (C) L.J.M. de Wit 1989    *
X *                                                                           *
X * This software may be used and distributed freely if not used commercially  *
X * and the originator (me) is mentioned in the source (just leave this 9 line *
X * header intact).                                                           *
X *                                                                           *
X *****************************************************************************
X *
X * sortcomp.c: comparision functions
X *
X * These functions contain the numeric comparision functions c_n and its
X * reverse, c_nr. The other 48 comparision functions are formed by combining
X * the following properties (take note of the Capitals):
X *  a) either Dictionary, Ignore non-printables or Any other        (3)
X *  b) ignore leading Blanks, versus not ignoring them              (2)
X *  c) Fold upper case to lower, versus not folding                 (2)
X *  d) Reverse the result of the comparision, versus not reversing  (2)
X *  e) Unbounded (bounded only by '\0'), versus upper limit bound   (2)
X *
X * Since comparing is done a lot it is important for the compare functions
X * to be fast. As for using the 48 functions as it stands the following
X * arguments are used:
X * One could have combined functions and used flags to discern between options.
X * This would however involve passing more parameters to the function (the
X * flags) and would require (perhaps a lot of) unwanted testing inside the
X * function.
X * Several functions call one of the other functions. This has been done in
X * such a way that duplication of code is mostly prevented, but still this call
X * is limited to only one (both in number and in level).
X * The numerical compare could have been done by a simple atoi(), but the
X * c_n function does the comparision inline, and stops comparing when the
X * bigger one has been found (while atoi needs to do calculation ala
X * 10 * num + digit, and will use all digits).

X * sortfile.c: stdio replacement for Atari ST
X *
X * This replacement is added both to speed up the normal stdio offered by
X * Lattice C, and to repair a bug with open() (fopen() ?) that is in the
X * standard library (version 3.03: try opening & closing 20 files, your
X * program bombs when you try to open a new file, even though the old ones
X * have been closed).
X *
X * Note that this package is not complete (no flushbuf, filbuf, printf etc.)
X * but this wasn't the intent anyway; furthermore, the allocation of buffers
X * takes place when a file is opened, rather than when it is first read/written
X * (as in a standard stdio package).

            **** Client-Side Information ****

                UW (Unix (tm) Windows) ST
          A Windowing Terminal Emulator for the Atari ST

This program was written by Hans-Martin Mosner at the University of
Dortmund in West Germany.  It has since been enhanced by Brad Bosch
and Brian Katzung at Lachman Associates, Inc., in Naperville, Illinois.
We have added quite a lot, including

     o keyboard and mouse locking,
     o simple text capture,
     o kermit file transfer in a uw window,
     o subprocess execution,
     o function-key support,
     o RS232 configuration,
     o additional fonts, and
     o printer support.

Limitations:
     o only supports monochrome systems
     o only supports adm31 emulation
       (but the emulation has been "enhanced"--see README)
     o only supports the minimum UW protocol
```

We have spent a great deal of effort trying to work out or around bugs
in GEM, HMM's code, and our code, but I'm sure some have succeeded in
eluding us even though this code has been in use at Lachman Associates
for over a year.

**** Server Information ****

The latest Unix(tm)-side server that we know of is version 4.1.2.
The author and contact person is:

     John D. Bruner
     ARPANET/MILNET: jdb@s1-c.ARPA
     UUCP: {seismo,ut-sally,dual,lll-crg}!mordor!jdb

X *  r p a c k
X *
X *  Read a Packet
X *  This routine is called both to buffer data from the host to the kermit
X *  window and to retreive those buffers once they contain a packet.  This
X *  routine calls the kermit state machine when it has a complete packet.
X *  The kermit state machine in turn calls this routine to retreive the packet.
X *  Thus, this routine is indirectly recursive to two levels.  Receive timeouts
X *  and bad packets cause FALSE to be returned to the state machine.  The uw
X *  control loop calls us with num == NULL to pass us a string of data from
```

```
X *  the host.  The uw control loop calls us with len == NULL if the timout
X *  counter (kerm_time) exceeds timint without us reseting it.
X */

X
X        UW (Unix (tm) Windows) for the Atari ST
X
XThis program was written by Hans-Martin Mosner at the University of
XDortmund in West Germany.  It has since been enhanced by Brad Bosch
Xand Brian Katzung at Lachman Associates, Inc., in Naperville, Illinois.
X
XNote that this disk represents a beta test version, and is provided on
Xa strictly as-is basis, and we assume no responsibility or liability
Xfor any aspect of this software.
X
XThis version of uw provides only adm31 emulation and the most basic
XUW protocol.  The adm31 emulation has been extended slightly.  See
Xthe end of the Features section for a description of the extensions.
X
XFeatures added by Brad Bosch and Brian Katzung:
X
X    o Jump scrolling occurs if screen updates can't keep up with
X      transmission from the host.
X
X    o The input window may be different than the top window.
X
X    o A printer copy of output to each window may be enabled or
X      disabled on a window-by-window basis in various flavors.
X
X    o <Shift><Help> sends a break.
X
X    o There is a menu item to reset flow control if the Atari and
X      the host get out of synchronization.
```

X
X   o Fonts "windalt.fnt", "windoth.fnt", and "windtny.fnt" are
X   supported in addition to "windstd.fnt". The "windtny" font is
X   small enough to allow four 24 x 80 windows on the screen without
X   overlapping.
X
X   o The smaller system font is offered in addition to the larger
X   one. Some of the characters in the smaller font are "improved"
X   to increase readability.
X
X   o The user may now select whether or not a window will be
X   "topped" when a ^G (BEL) is output to it.
X
X   o The user may choose to have ^G (BEL) flash the screen, ring
X   the bell, neither, or both.
X
X   o When not selecting an input window, pressing the right mouse
X   button on the menu bar toggles the menu bar sensitivity.
X
X   o The close-box works even when the UW protocol is not running.
X   This is useful for changing the font size or other options.
X
X   o The RTS (request to send) and DTR (data terminal ready) lines
X   can be cleared and asserted.
X
X   o Function keys can be used and defined up to 40 characters each.
X
X   o Function keys and other global option values can be saved and
X   loaded. A file called "win.cnf", if present, is read at startup
X   time.
X
X   o The right mouse button can be used to copy text from the screen
X   and send it to a window as keyboard input. Click twice on a
X   window border to send copied text. Click once on the boarder to
X   select the window for input. Select text by dragging with the
X   right button pressed. Inside a border, a single right button
X   click selects a word and a double click selects a line.
X
X   o Emulation window size can now be selected when a window is opened.
X   The fixed sizes available in the menu can be changed with a resource
X   editor without recompiling. Default sizes are font dependent.
X
X   o A window menu item was added to allow the bottom window to be sent
X   to the top even if it is competely hidden. Another item sends the
X   top window to the bottom. The latter is somewhat slow due to
X   shortcomings in GEM.
X
X   o The main keyboard digit keys when used while the alt key is down
X   will select that window number to be the top and keyboard input
X   window. The first window is alt-1, the last is alt-7. Windows
X   are numbered as gem numbers them. Alt-key bindings for lower
X   case letters are scanned from the menu strings in the resource
X   file. These bindings are indicated by the ^E (close box)

```
X      character.
X
X    o A window menu item was added to shrink the current window to an
X      iconic size.  The second-from-the-top non-iconic window becomes
X      the current window.  The fuller box is used to reverse the process.
X
X    o An option is now available to cause new windows to be created
X      without the sliders and arrows. The title bar (and close and
X      fuller boxes) may also be eliminated by another option.  Menu
X      items have been added to support most of the functionality lost
X      when the window controls are turned off.
X
X    o Additional help information was added to the about dialog.
X
X    o Startgem is now included in the distribution.  This program, if
X      placed in the auto folder, will attempt to start a:\bin\uw.prg
X      automatically when the ST is booted up.
X
X    o A variable called "locpath" contains the name of a directory to
X      scan after the current directory when looking for configuration
X      and font files.  The string is 64 bytes long and defaults to
X      c:\bin.
X
X    o An RS232 configuration dialog has been added.  There is no pro-
X      vision for putting this information in the configuration file.
X      Bug view:  There is no auto-configuration.  Feature view:  Changes
X      persist across executions.
X
X    o One can now capture host output to a file on a per-window basis.
X      Capture mode is terminated by setting an empty file name.
X
X    o Added keyboard lock to file menu.  This locks the keyboard and mouse
X      until your password is reentered.
X
X    o Added change working directory item to file menu.  This is usefull
X      for kermit and the exec command entry.
X
X    o Added execute command entry.  This allows uw to be suspended while
X      another command is executed.  Note that mwc startup for gem does not
X      preserve the environment variables.  The default command and
X      parameters are part of the config file.
X
X    o Add basic kermit functionality.  Kermit can operate under the uw
X      protocol in a window concurent with interactive terminal windows.
X      Sending multiple files is not yet supported.
X
X
XExtensions to Adm31 emulation:
X
X    o If the host sends a window the sequence ESC [18t, the window will
X      respond with ESC [8;<rows>;<cols>t, where <rows> and <cols> specify
X      the window's size in characters.
X
```

```
X    o The insert line and delete line escape sequences (ESC E and ESC R,
X      respectively) allow a repeat count (ie, ESC 5E inserts 5 lines).
X
XBugs fixed:
X
X    o Exiting in "fast" mode used to leave a window open.  The
X      system would crash on the next run unless you had returned
X      to the desktop.
X
X    o Actions on windows now check that there are windows to act upon.
X
X
XKnown bugs:
X
X    o Because of the extra memory used in the jump scrolling
X      algorithm, the bottom row of pixels of an earlier line
X      sometimes appears immediately below the title bar.
X
X    o GEM doesn't let you completely eliminate the menu bar and
X      increase your workspace.
X
X    o Desk accessories sometimes leave damage on the screen.
X
X    o GEM doesn't send "top" messages to the top window, so you
X      can't use the left mouse button as a short hand to select
X      the top window for input.  Use the right button on the window
X      title bar instead.
X
X    o The rsconf() baud rates listed in the manual as 75 and 50 baud
X      really result in system timer settings for 120 and 80 baud.
X      The RS232 configuration dialog allows you to set these two baud
X      rates, but decodes them as 300 or 200 baud, respectively.
X
X    o The RS232 configuration code uses some trickery to determine the
X      current port configuration.  Some parts of this code may need to
X      be turned off or adapted to run on other hardware or if system
X      calls stop returning undocumented values.
SHAR_EOF
chmod 0600 README || echo "restore of README fails"
sed 's/^X//' << 'SHAR_EOF' > RESETAUX.S &&
X/
X/ Reset the Aux rs232 port.  Usage:
X/   char *rs232_iorec = Iorec(0);    /* Do this first   */
X/
X/   if (rs232_reset())
X/       Cauxout(0x11);          /* sent an XOFF        */
X/
X/ This subroutine was written by Martin Minow, Arlington, MA
X/ and is in the public domain.
X/
X/   .shrd                   / Public data
X/   .globl    rs232_iorec_       / -> aux io record. see below
X    .shri                   / Public instructions
```

```
X    .globl   rs232_reset_
X
Xrs232_reset_:
X    move.l   d2,-(sp)      / Save a scratch register
X    clr.l    -(sp)             / Super(0L) switches to super mode
X    move.w   $0x20,-(sp)       / Super opcode
X    trap $1           / Call TOS
X    addq.l   $6,sp             / Clear stack
X    move.l   d0,-(sp)      / Save old stack for now.
X/
X/ If you don't already have the iorec as a readily-available global,
X/ uncomment the following code (which is, of course, untested)
X/
X    clr.w    -(sp)             / Aux port is device zero
X    move.w   $14,-(sp)     / Iorec
X    trap $14          / Xbios(14)
X    addq.l   $4,sp             / Clear stack
X/ End of "get iorec" code. We already have this information:
X/   movea    rs232_iorec_,a0        / a0 -> I/O record
X    movea    d0,a0             / a0 -> I/O record
X    move sr,-(sp)      / Save cpu status
X    ori  $0x700,sr     / Disable interrupts
X/   clr.l    6(a0)             / Clear input  head, tail -- crashes!
X    clr.l    20(a0)            / Clear output head, tail
X    clr.l    d2            / Clear result
X    or.b 30(a0),d2     / Get old rcv xoff state
X    clr.w    30(a0)            / Cancel rcv, xmt xoff states
X    move (sp)+,sr      / Enable interrupts
X    move.w   $0x20,-(sp)       / Super -- old_stack is still at (sp)
X    trap $1           / Exit super mode
X    addq $6,sp             / Clean junk from stack
X    move.l   d2,d0             / Get result
X    move.l   (sp)+,d2      / Restore d2
X    rts               / Exit routine

X/
X/   STARTGEM.S    6-MAR-1987    by GHOST-Soft
X/
X/   This program is used to start GEM programs from within the AUTO folder.
X/
X/   The code is probably highly nonportable, as it heavily depends on the
X/   internal organisation of code in TOS/GEM.
X/   As this program works with ROM- as well as all disk-based versions
X/   of German TOS, I'm pretty sure that this program works with foreign
X/   versions of TOS, too.
X/   All addresses given in square brackets apply to the German ROM-TOS.
X/
X/   Assemble with Mark Williams assembler:
X/        as -o startgem.o startgem.s
X/        gemfix startgem.o startgem.prg
X/        strip startgem.prg
X/             _or_
X/        as -o startgem.o startgem.s
X/        ld -o startgem.prg -s startgem.o
X/

X/*
X *  uw command bytes
X *
X * Copyright 1985 by John D. Bruner.  All rights reserved.  Permission to
X * copy this program is given provided that the copy is not sold and that
X * this copyright notice is included.
X *
X *
X * Two types of information are exchanged through the 7-bit serial line:
X * ordinary data and command bytes.  Command bytes are preceeded by
X * an IAC byte.  IAC bytes and literal XON/XOFF characters (those which
X * are not used for flow control) are sent by a CB_FN_CTLCH command.
X * Characters with the eighth bit set (the "meta" bit) are prefixed with
X * a CB_FN_META function.
X *
X * The next most-significant bit in the byte specifies the sender and
X * recipient of the command.  If this bit is clear (0), the command byte
X * was sent from the host computer to the Macintosh; if it is set (1)
X * the command byte was sent from the Macintosh to the host computer.
X * This prevents confusion in the event that the host computer
X * (incorrectly) echos a command back to the Macintosh.
X *
X * The remaining six bits are partitioned into two fields.  The low-order
X * three bits specify a window number from 1-7 (window 0 is reserved for
X * other uses) or another type of command-dependent parameter.  The next
X * three bits specify the operation to be performed by the recipient of
X * the command byte.
X *
X * Note that the choice of command bytes prevents the ASCII XON (021) and
X * XOFF (023) characters from being sent as commands.  CB_FN_ISELW commands
X * are only sent by the Macintosh (and thus are tagged with the CB_DIR_MTOH
X * bit).  Since XON and XOFF data characters are handled via CB_FN_CTLCH,
X * this allows them to be used for flow control purposes.

Posting-number: Volume 2, Issue 24
Archive-name: uuduue

Here are the latest sources of Dumas' UUD/UUE package. They
were posted a while ago here in europe. They are *not*
uuencoded to give you a chance to retrieve them.

Submitted-by: csrobe@cs.wm.edu (Chip Roberson)
Posting-number: Volume 2, Issue 25
Archive-name: mwstring

Here is a reasonable implementation of the Draft Proposed American National
Standard (dpANS) header file for strings in C.  It should be reasonably
consistent with the dpANS while representing MWC's implementation.

Enjoy,
-c

Submitted-by: john@logajan.mn.org (John Logajan)
Posting-number: Volume 2, Issue 26
Archive-name: mailtruk

Below are five files generically named MailTruk Release V1.0.
MailTruk is a GFA Basic (2.0) implementation of uucp/uucico.
MailTruk is intended to allow non-unix/non-C Atari ST's email
access to the Usenet community.

XINTRODUCTION TO THE NETWORK
X
XWelcome to the world of uucp style data exchange. Uucp stands for
XUnix to Unix copy. Unix is an operating system used by a large
Xnumber of computers. A large network of computers running uucp
Xcompatible data exchange has evolved over the last several years.
XThis network encompasses university, corporate, governmental, and
Xindividually owned computers. It is estimated that there are over
X10,000 computers on the net, with approximately 400,000 users.
XThe two primary functions of the net are private electronic mail
Xand "broadly cast" electronic news transfer. The Usenet News
Xconsists of some 350 subject categories into which several
Xthousand articles a day are posted by users. An average day's
Xnews is typically four million characters -- and growing. Anyone
Xreceiving a full newsfeed is more and more feeling the need for
Xfaster data communications links, since such volume at 2400 baud
Xrequires five hours if uncompressed or 2.5 hours if compressed.
X
X
XINTRODUCTION TO THE MAILTRUK, READMAIL, AND WRITMAIL PROGRAMS
X
XMailTruk, ReadMail, and WritMail are uucp compatible
Xcommunications programs that run on Atari ST computers.   The
Xprograms are written in GFA Basic (2.0) and are freely distributed
Xas a readable listings in the public domain. Files included in
Xthe distribution include:
XMAILTRUK.LST, READMAIL.LST, WRITMAIL.LST, MAILTRUK.DOC,
XPROTOCOL.DOC
X
XWritMail is used to write your outgoing mail. Writmail's main
Xtask is to format your message so that other computers on the net
Xrecognize what you have sent and where it is going. Each, in
Xturn, passes it along until it hopefully reaches your intended
Xrecipient.
X
XMailTruk is the actual communications program. It first dials
Xyour neighbor site, establishes protocol agreement, and then sends
Xthe messages, if any, that you have previously prepared with
XWritMail. When MailTruk has finished sending, it requests to
Xreceive any mail that the remote site has pending for you. After
Xit receives all incoming mail, MailTruk terminates the connection.
X
XReadMail allows you to read your mail in a convenient manner. The
Xmain objection to reading you mail files directly with GEM
Xcommands is that Unix machines use linefeed characters as end-of-
Xline indicators rather than the carriage return character used by

XGEM. Thus, direct reading of mail files results in a confusing
Xpresentation.
X
XAlthough MailTruk can transfer the file types used to send the
XNetwork News, additional file pre- and post-processing is required
Xto read or write News articles. ReadMail and WritMail DO NOT
Xhandle the News format. Uncompressed News would be a fairly
Xstraight forward task to handle, but compressed and batched News
Xwill require additional sophistication. Let me know if you feel
Xmotivated to write such a program!
X
X
XSETTING EVERYTHING UP
X
XFirst -- You need a site to call, account information for that
Xsite, and a modem. Since this program is being distributed over
Xthe net, if you track back from where this program came from,
Xyou're bound to run into somebody who knows your local net
Xarrangement. (I pay $25 a year to a guy who runs a "domain park"
Xfor my access. He, in turn, calls other bigger sites -- and so
Xon.)
X
XSecond -- All mail going to a particular site is placed in its own
Xdirectory. All mail coming to your site is placed in its own
Xdirectory. You should create these directories before running the
Xprograms. I am site -logajan-, I call one site -bungia-. So, I
Xcreated a directory called MAIL on my C: drive where I put all my
Xprograms, and I created two sub-directories, BUNGIA and LOGAJAN,
Xi.e. C:\MAIL\BUNGIA\
X   C:\MAIL\LOGAJAN\
X
XThird -- All three programs are totally self-contained in that
Xthey do not share an external common configuration file. So you
Xwill have to insure that each of the important variables,
Xincluding the directory names mentioned above, in each of the
Xprograms is correct and consistent. The variables are grouped
Xnear the beginning of each program. You WILL have to customize
Xthese variables for these programs to work!
X
XFourth -- If you have multiple sites to call, you will have to
Xmake multiple versions of the MailTruk program (or modify it to
Xhandle multiple cases.) You will also want to write a program
Xthat recognizes messages which are just passing through, and
X"rewrites" the pertinent addresses, and places them back out in
Xthe outbound message area.
X
XFifth -- Otherwise you are a "leaf" site (you only call one
Xmachine) and any mail with your machine name in it is assumed to
Xbe to you, no matter what user name or additional path is in the
XTo: address line.
X
XSixth -- Paths; the From: and To: portion of messages; are a
Xsomewhat mysterious subject. Basically you have to know, at a

```
Xminimum, the recipient's user-name and machine-name, and the path
Xto the nearest smart mailer site.   Otherwise you can specify the
Xentire path -- but some smart sites end up sending it the route
Xthey think is best anyhow.
X
X  If I want to send to jack at atari, I enter the path as:
X     bungia!atari!jack     Note:  nearest!next!next!farthest!user
X     (my neighbor, bungia, knows the tortuous route to atari)
X
X  or bungia!umn-cs!rutgers!att.att.com!wally if I want to get to
X     wally at att and know the complete path.
X
XYou will often see @'s and %'s in paths.  Basically you just read
Xthese in the other direction, i.e.:
X
X     john@logajan.mn.org@bungia@shamash@nic.mr.net   is an actual
X     path TO my machine from nic.mr.net.
X
XHowever, note that WritMail forces you to state the path with at
Xleast one (!) symbol.  Your neighbor's machine is always the first
Xname in the path, therefore you could do:
X
X     bungia!ben@franklin.electric.com
X
X
XSeventh -- Hopefully there is enough information in the listings
Xfor you to set up your own site and get it operational.
X                           Good luck.
X

XGeneral
X
X                            The  technique  depends  on  the
Xnotion of a transmission window to determine upper and lower
Xbounds  for  valid  sequence  numbers.   The  transmitter is
Xallowed to retransmit packets having sequence numbers within
Xthe  window  until  the receiver indicates that packets have
Xbeen correctly received.  Positive acknowledgement from  the
Xreceiver  moves  the  window; negative acknowledgement or no
Xacknowledgement causes retransmission.   The  receiver  must
Xignore  duplicate  transmission,  detect  the various errors
Xthat may occur, and inform the transmitter when packets  are
Xcorrectly or incorrectly received.
X
XPacket Formats
X
X     The protocol is defined in terms of  message  transmis-
Xsions  of  8-bit  bytes.   Each message includes one control
Xbyte plus a data segment of zero or more information  bytes.
XThe  allowed data segment sizes range between 32 and 4096 as
Xdetermined by the formula 32(2k) where k is a 3-bit  number.
```

XThe packet sequence numbers are likewise constrained to 3-
Xbits; i.e. counting proceeds modulo-8.
X
X   The control byte is partitioned into three fields as
Xdepicted below.
X
Xbit   7   6   5   4   3   2   1   0
X   t   t   x   x   x   y   y   y
X
XThe t bits indicate a packet type and determine the
Xinterpretation to be placed on the xxx and yyy fields. The
Xvarious interpretations are as follows:
X
X   tt   interpretation
X
X   00   control packet
X   10   data packet
X   11   short data packet
X
XA data segment accompanies all non-control packets. Each
Xtransmitter is constrained to observe the maximum data seg-
Xment size established during initial synchronization by the
Xreceiver that it sends to. Type 10 packets have maximal
Xsize data segments. Type 11, or short, packets have zero
Xor more data bytes but less than the maximum. The first one
Xor two bytes of the data segment of a short packet are
Xcount bytes that indicate the difference between the max-
Ximum size and the number of bytes in the short segment. If
Xthe difference is less than 127, one count byte is used. If
Xthe difference exceeds 127, then the low-order seven bits of
Xthe difference are put in the first data byte and the high-
Xorder bit is set as an indicator that the remaining bits of
Xthe difference are in the second byte.
X
X   The sequence number of a non-control packet is given by
Xthe xxx field. Control packets are not sequenced. The
Xnewest sequence number, excluding duplicate transmissions,
Xaccepted by a receiver is placed in the yyy field of non-
Xcontrol packets sent to the other receiver.
X
X   There are no data bytes associated with a control
Xpacket, the xxx field is interpreted as a control message,
Xand the yyy field is a value accompanying the control mes-
Xsage. The control messages are listed below in decreasing
Xpriority. That is, if several control messages are to be
Xsent, the lower-numbered ones are sent first.
X
X   xxx   name   yyy
X
X   1   CLOSE   n/a
X   2   RJ   last correctly received sequence number
X   3   ---   ---
X   4   RR   last correctly received sequence number

X   5   INITC   window size
X   6   INITB   data segment size
X   7   INITA   window size
X
X   The CLOSE message indicates that the communications Xchannel is to be shut down. The RJ, or reject, message Xindicates that the receiver has detected an error and the Xsender should retransmit after using the yyy field to update Xthe window. The RR, or receiver Xready, message indicates that the receiver has detected no Xerrors; the yyy field updates the sender's window. The XINITA/B/C messages are used to set window and data segment Xsizes. Segment sizes are calculated by the formula 32(2yyy) Xand window sizes may range between 1 and 7.
X
X   Measurements of the protocol running on communication Xlinks at rates up to 9600 baud showed that a window size of X2 is optimal given a packet size greater than 32 bytes. XThis means that the link bandwidth can be fully utilized by Xthe software.
X
XMessage Exchanges
X
X   Initialization
X
X   Messages are exchanged between four cooperating enti- Xties: two senders and two receivers. This means that the Xcommunication channel is thought of as two independent Xhalf-duplex data paths. For example the window and segment Xsizes need not be the same in each direction.
X
X   Initial synchronization is accomplished with two 3-way Xhandshakes: two each of INITA/INITB/INITC. Each sender Xtransmits INITA messages repeatedly. When an INITA message Xis received, INITB is sent in return. When an INITB message Xis received and an INITB message has been sent, an INITC Xmessage is sent. The INITA and INITB messages carry with Xthem the packet and window size that each receiver wants to Xuse, and the senders are supposed to comply. When a Xreceiver has seen all three INIT messages, the channel is Xconsidered to be open. INIT messages are ignored elsewhere.
X
X   Data Transport
X
X   After initial synchronization each receiver sets a Xmodulo-8 incrementing counter R to 0; each sender sets a Xsimilar counter S to 1. The value of R is always the number Xof the most recent correctly received packet. The value of XS is always the first sequence number in the output window. XLet W denote window size. Note that the value of W may be Xdifferent for each sender.
X
X   A sender may transmit packets with sequence numbers in

Xthe range S to (S+W-1) mod-8. At any particular time a Xreceiver expects arriving packets to have numbers in the Xrange (R+1) mod-8 to (R+W) mod-8. Packets must arrive in Xsequence number order are are only acknowledged in order. XThat is, the next packet a receiver will acknowledge must Xhave sequence number (R+1) mod-8.
X
X A receiver acknowledges receipt of data packets by Xarranging for the value of its R counter to be sent across Xthe channel where it will be used to update an S counter. XThis is done in two ways. If data is flowing in both direc-Xtions across a channel then each receiver's current R value Xis carried in the yyy field of non-control packets. Other-Xwise when there is no bidirectional data flow, each Xreceiver's R value is transmitted across the link as the yyy Xfield of an RR control packet.
X
X Error handling is up to the discretion of the receiver. XIt can ignore all errors in which case transmitter timeouts Xmust provide for retransmission. The receiver may also gen-Xerate RJ error control packets. The yyy field of an incom-Xing RJ message replaces the S value of the local sender and Xconstitutes a request for retransmission to start at that Xsequence number.
X
X Termination
X
X The CLOSE message is used to terminate communications. XSoftware on either or both ends of the communication channel Xmay initiate termination. In any case when one end wants to Xterminate it sends CLOSE messages until one is received from Xthe other end or until a programmable limit on the number of XCLOSE messages is reached. Receipt of a CLOSE message Xcauses a CLOSE message to be sent.
X
X Framing
X
X The term framing is used to denote the technique by Xwhich the beginning and end of a message is detected in a Xbyte stream; error control denotes the method by which Xtransmission errors are detected.
X
X A six byte framing envelope is constructed using the Xcontrol byte C of a packet and five other bytes as depicted Xbelow.
X <DLE><k><c0><c1><C><x>
XThe <DLE> symbol denotes the ASCII ctrl/P character. If the Xenvelope is to be followed by a data segment, <k> has the Xvalue log2(size)-4; i.e. 1 < k < 8. If k is 9, then the Xenvelope represents a control packet. The <c0> and <c1> Xbytes are the low-order and high-order bytes respectively of Xa 16-bit checksum. For control packets, this value is X0xAAAA minus the control byte C.

```
XFor data packets,  the  checksum  is calculated by a program.
X(John Logajan's 68000 version is below.)
XThe <x> byte is the exclusive-or of  <k><c0><c1><C>.   Error
Xcontrol  is  accomplished  by  checking  a  received framing
Xenvelope for compliance with the definition, and comparing a
Xchecksum function of the data segment with <c0><c1>.
X
X     This particular framing strategy assumes data  segments
Xare constant-sized: the  unused  bytes in a short packet are
Xactually transmitted.
X

Archive-name: format83

This program will read a binary file and output in Intel ASCII Hex
format to standard out. This is one of the most common translation formats
for transfer to emulators and PROM programmers.

X      This program will read a binary file and output in Intel ASCII Hex
Xformat to standard out. This is one of the most common translation formats
Xfor transfer to emulators and PROM programmers. This format can also be read
Xdirectly by the debugger supplied with both MSDOS and CPM if the extension
Xis ".HEX". I.E. if you use "format83 filename.bin> filename.hex" and then
Xload filename.hex with the debugger, you will be looking at your original
Xbinary file. If you modify the program, this is an excellent way to test
Xyour modifications.
X      This program was not written to be efficient, tricky, or elegant.
XIt was written to be easily understood, modified, and/or ported to any
Xsystem, including 8 bit systems with C compilers. Oh yeah, and it also
Xwas written because it was useful. It is free and I am releasing it to
Xthe public domain. You can do whatever you want with it. If you can get
Xsomeone to pay you for it, you have my blessing.
X      This program will not solve all your problems! One of the trickiest
Xparts about using the serial port of your garden variety PC is getting the
Xcabling and parameters right on the serial port. I have included a small
Xhex file (contents "hello world\n" :-) which I suggest you use to verify
Xyour connection with. Until you can "copy test.hex com1:" without getting
Xerrors, do not expect to be able to transfer anything meaningful to your
Xprogrammer. This program *does* work, I use it exclusively for tranferring
Xbinary files to the Data I/O programmers I use here, but it was written by
Xme personally for my own use and is not supported by Data I/O. If you do use
Xthis with a Data I/O programmer, select transfer format 83 before starting.
XIf you don't rename this program, it will impossible for you to forget :-)

```

The following sources (in shar format) replace and obsolete the
previous version of the programs.

Below are five files generically named MailTruk Release V1.1.
MailTruk is a GFA Basic (2.0) implementation of uucp/uucico.
MailTruk is intended to allow non-unix/non-C Atari ST's email
access to the Usenet community. The five files included below,
in order are: MAILTRUK.DOC, MAILTRUK.LST, WRITMAIL.LST,
READMAIL.LST, and PROTOCOL.DOC.   Thanks -- John Logajan.

```
#       This is a shell archive.
#       Remove everything above and including the cut line.
#       Then run the rest of the file through sh.
#----cut here-----cut here-----cut here-----cut here----#
#!/bin/sh
# shar: Shell Archiver
#       Run the following text with /bin/sh to create:
#       mailtruk.doc
#       mailtruk.lst
#       writmail.lst
#       readmail.lst
#       protocol.doc
cat << \SHAR_EOF > mailtruk.doc
                      MailTruk Documentation
                                by
                    John Logajan, March 1989
                         4248 Hamline Ave
                       Arden Hills, MN  55112
                        john@logajan.mn.org

Note:  V1.1 seems to work on 512k machines, whereas V1.0
       apparently did not.  Both V1.1 and V1.0 work on
       1 meg machines.

INTRODUCTION TO THE NETWORK

Welcome to the world of uucp style data exchange.  Uucp stands for
Unix to Unix copy.  Unix is an operating system used by a large
number of computers.  A large network of computers running uucp
compatible data exchange has evolved over the last several years.
This network encompasses university, corporate, governmental, and
individually owned computers.  It is estimated that there are over
10,000 computers on the net, with approximately 400,000 users.
The two primary functions of the net are private electronic mail
and "broadly cast" electronic news transfer.  MailTruk is the
mechanism that transports both the news and email, however this
release of MailTruk support software does not include news reading
interfaces.

INTRODUCTION TO THE MAILTRUK, READMAIL, AND WRITMAIL PROGRAMS
```

MailTruk, ReadMail, and WritMail are uucp compatible communications programs that run on Atari ST computers. The programs are written in GFA Basic (2.0) and are freely distributed as readable listings in the public domain. Files included in the distribution are:
MAILTRUK.LST, READMAIL.LST, WRITMAIL.LST, MAILTRUK.DOC, PROTOCOL.DOC

WritMail is used to write your outgoing mail. Writmail's main task is to format your message so that other computers on the net recognize what you have sent and can figure out where it is going. Each machine, in turn, passes it along until it hopefully reaches the intended recipient.

MailTruk is the actual communications program. It first dials your neighbor site, establishes protocol agreement, and then sends the messages, if any, that you have previously prepared with WritMail. When MailTruk has finished sending, it requests to receive any mail that the remote site has pending for you. After it receives all incoming mail, MailTruk terminates the connection.

ReadMail allows you to read your mail in a convenient manner. The main objection to reading you mail files directly with GEM commands is that Unix machines use linefeed characters as end-of-line indicators rather than the carriage return character used by GEM. Thus, direct reading of mail files results in a confusing presentation.

Although MailTruk can transfer the file types used to send the Network News, additional file pre- and post-processing is required to read or write News articles. ReadMail and WritMail DO NOT handle the News format. Uncompressed News would be a fairly straight forward task to handle, but compressed and batched News would require additional sophistication. Let me know if you feel motivated to write such a program!

SETTING EVERYTHING UP

First -- You need a site to call, logon information for that site, and a modem. Since this program is being distributed over the net, if you track back from where this program came from, you're bound to run into somebody who knows your local net arrangement. (I pay $25 a year to a guy who runs a "domain park" for my access. He, in turn, calls other bigger sites -- and so on.)

Second -- All mail going to a particular site is placed in its own directory. All mail coming to your site is placed in its own directory. You should create these directories before running the programs. I am site -logajan-, I call one site -bungia-. So, I created a directory called MAIL on my C: drive where I put all my programs, and I created two sub-directories, BUNGIA and LOGAJAN, i.e. C:\MAIL\BUNGIA\

C:\MAIL\LOGAJAN\

Third -- All three programs are totally self-contained in that they do not share an external common configuration file. So you will have to insure that each of the important variables in each of the programs is correct and consistent, including the directory names mentioned above. The variables are grouped near the beginning of each program. You WILL have to customize these variables for the programs to work!

Fourth -- If you have multiple sites to call, you will have to make multiple versions of the MailTruk program (or modify it to handle multiple cases.) You will also want to write a program that recognizes messages which are just passing through, and "rewrites" the pertinent addresses, and places them back out in the outbound message area.

Fifth -- Otherwise you are a "leaf" site (you only call one machine) and any mail with your machine name in it is assumed to be to you, no matter what user name or additional path is in the To: address line.

Sixth -- The MailTruk program is designed to dail out only. If you want to re-write MailTruk to answer incoming calls -- feel free. Just remember that everthing occurs in reverse.

Seventh -- Paths; the From: and To: portion of messages; are a somewhat mysterious subject. Basically you have to know, at a minimum, the recipient's user-name and machine-name, and the path to the nearest smart mailer site. Otherwise you can specify the entire path -- but some smart sites end up sending it the route they think is best anyhow.

If I want to send to jack at atari, I enter the path as:
bungia!atari!jack Note: nearest!next!next!farthest!user
(my neighbor, bungia, knows the tortuous route to atari)

or bungia!umn-cs!rutgers!att.att.com!wally if I want to get to wally at att and know the complete path.

You will often see @'s and %'s in paths. These are Internet style paths, such as:

john@logajan.mn.org

However, note that WritMail forces you to state the path with at least one (!) symbol. Your neighbor's machine is always the first name in the path, therefore you could do:

bungia!ben@franklin.electric.com

Eighth -- Hopefully there is enough information in the listings

```
for you to set up your own site and get it operational.
                          Good luck.

                  Packet Driver Protocol

                       G. L. Chesson
                     Bell Laboratories
                (Shortened by John Logajan)
General

                            The technique depends on the
notion of a transmission window to determine upper and lower
bounds for valid sequence numbers.  The transmitter is
allowed to retransmit packets having sequence numbers within
the window until the receiver indicates that packets have
been correctly received.  Positive acknowledgement from the
receiver moves the window; negative acknowledgement or no
acknowledgement causes retransmission.  The receiver must
ignore duplicate transmission, detect the various errors
that may occur, and inform the transmitter when packets are
correctly or incorrectly received.

Packet Formats

     The protocol is defined in terms of message transmis-
sions of 8-bit bytes.  Each message includes one control
byte plus a data segment of zero or more information bytes.
The allowed data segment sizes range between 32 and 4096 as
determined by the formula 32(2k) where k is a 3-bit number.
The packet sequence numbers are likewise constrained to 3-
bits; i.e. counting proceeds modulo-8.

     The control byte is partitioned into three fields as
depicted below.

bit     7      6      5      4      3      2      1      0
        t      t      x      x      x      y      y      y

The t bits indicate a packet type and determine the
interpretation to be placed on the xxx and yyy fields.  The
various interpretations are as follows:

          tt      interpretation

          00      control packet
          10      data packet
          11      short data packet

A data segment accompanies all non-control packets.  Each
transmitter is constrained to observe the maximum data seg-
```

ment size established during initial synchronization by the receiver that it sends to. Type 10 packets have maximal size data segments. Type 11, or short, packets have zero or more data bytes but less than the maximum. The first one or two bytes of the data segment of a short packet are count bytes that indicate the difference between the maximum size and the number of bytes in the short segment. If the difference is less than 127, one count byte is used. If the difference exceeds 127, then the low-order seven bits of the difference are put in the first data byte and the high-order bit is set as an indicator that the remaining bits of the difference are in the second byte.

The sequence number of a non-control packet is given by the xxx field. Control packets are not sequenced. The newest sequence number, excluding duplicate transmissions, accepted by a receiver is placed in the yyy field of non-control packets sent to the other receiver.

There are no data bytes associated with a control packet, the xxx field is interpreted as a control message, and the yyy field is a value accompanying the control message. The control messages are listed below in decreasing priority. That is, if several control messages are to be sent, the lower-numbered ones are sent first.

xxx	name	yyy
1	CLOSE	n/a
2	RJ	last correctly received sequence number
3	---	---
4	RR	last correctly received sequence number
5	INITC	window size
6	INITB	data segment size
7	INITA	window size

The CLOSE message indicates that the communications channel is to be shut down. The RJ, or reject, message indicates that the receiver has detected an error and the sender should retransmit after using the yyy field to update the window. The RR, or receiver ready, message indicates that the receiver has detected no errors; the yyy field updates the sender's window. The INITA/B/C messages are used to set window and data segment sizes. Segment sizes are calculated by the formula 32(2yyy) and window sizes may range between 1 and 7.

Measurements of the protocol running on communication links at rates up to 9600 baud showed that a window size of 2 is optimal given a packet size greater than 32 bytes. This means that the link bandwidth can be fully utilized by the software.

Message Exchanges

Initialization

Messages are exchanged between four cooperating entities: two senders and two receivers. This means that the communication channel is thought of as two independent half-duplex data paths. For example the window and segment sizes need not be the same in each direction.

Initial synchronization is accomplished with two 3-way handshakes: two each of INITA/INITB/INITC. Each sender transmits INITA messages repeatedly. When an INITA message is received, INITB is sent in return. When an INITB message is received and an INITB message has been sent, an INITC message is sent. The INITA and INITB messages carry with them the packet and window size that each receiver wants to use, and the senders are supposed to comply. When a receiver has seen all three INIT messages, the channel is considered to be open. INIT messages are ignored elsewhere.

Data Transport

After initial synchronization each receiver sets a modulo-8 incrementing counter R to 0; each sender sets a similar counter S to 1. The value of R is always the number of the most recent correctly received packet. The value of S is always the first sequence number in the output window. Let W denote window size. Note that the value of W may be different for each sender.

A sender may transmit packets with sequence numbers in the range S to (S+W-1) mod-8. At any particular time a receiver expects arriving packets to have numbers in the range (R+1) mod-8 to (R+W) mod-8. Packets must arrive in sequence number order are are only acknowledged in order. That is, the next packet a receiver will acknowledge must have sequence number (R+1) mod-8.

A receiver acknowledges receipt of data packets by arranging for the value of its R counter to be sent across the channel where it will be used to update an S counter. This is done in two ways. If data is flowing in both directions across a channel then each receiver's current R value is carried in the yyy field of non-control packets. Otherwise when there is no bidirectional data flow, each receiver's R value is transmitted across the link as the yyy field of an RR control packet.

Error handling is up to the discretion of the receiver. It can ignore all errors in which case transmitter timeouts must provide for retransmission. The receiver may also generate RJ error control packets. The yyy field of an incom-

ing RJ message replaces the S value of the local sender and constitutes a request for retransmission to start at that sequence number.

Termination

The CLOSE message is used to terminate communications. Software on either or both ends of the communication channel may initiate termination. In any case when one end wants to terminate it sends CLOSE messages until one is received from the other end or until a programmable limit on the number of CLOSE messages is reached. Receipt of a CLOSE message causes a CLOSE message to be sent.

Framing

The term framing is used to denote the technique by which the beginning and end of a message is detected in a byte stream; error control denotes the method by which transmission errors are detected.

A six byte framing envelope is constructed using the control byte C of a packet and five other bytes as depicted below.

<DLE><k><c0><c1><C><x>

The <DLE> symbol denotes the ASCII ctrl/P character. If the envelope is to be followed by a data segment, <k> has the value log2(size)-4; i.e. 1 < k < 8. If k is 9, then the envelope represents a control packet. The <c0> and <c1> bytes are the low-order and high-order bytes respectively of a 16-bit checksum. For control packets, this value is 0xAAAA minus the control byte C.
For data packets, the checksum is calculated by a program. (John Logajan's 68000 version is below.)
The <x> byte is the exclusive-or of <k><c0><c1><C>. Error control is accomplished by checking a received framing envelope for compliance with the definition, and comparing a checksum function of the data segment with <c0><c1>.

This particular framing strategy assumes data segments are constant-sized: the unused bytes in a short packet are actually transmitted.

Logajan's 68000 version of the checksum program,
as called from a GFA Basic C: call.

```
start: move.l 4(sp),a0      ;data packet start address
       move.w 8(sp),d1      ;data packet length
       move.w 10(sp),d2     ;command byte
       move.l #$ffff,d0
       clr.w d3
ck1:   rol.w #1,d0
```

```
       move.l d0,d4
       clr.l d5
       move.b (a0)+,d5
       add.w d5,d0
       move.w d0,d5
       eor.w d1,d5
       add.w d5,d3
       cmp.l d4,d0
       bgt.s ovck
       eor.w d3,d0
ovck:  sub.w #1,d1
       bne.s ck1
       and.w #$ffff,d2
       eor.w d0,d2
       move.w #$aaaa,d0
       sub.w d2,d0
       and.l #$ffff,d0      ;Checksum in D0.
       rts
```

*
* Translation Table
* =================
*
* This table provides translation from single Atari input bytes into
* multiple printer codes, and is useful for printing extraneous
* characters such as accented characters etc. All characters are
* subjected to translation, but if there is no entry in the table for
* a particular code, then the original code is sent to the printer.
*
* The entries must be arranged in ascending order of Atari input
* code. The table is NULL terminated.
*
* This table assumes that the HP DeskJet printer is set in
* PC8 Character Set (Switches A1 to A4 down)

0                                  * NULL: print a space

*
* Translation Table
* =================
*
* This table provides translation from single Atari input bytes into
* multiple printer codes,and is useful for printing extraneous
* characters such as accented characters etc. All characters are
* subjected to translation,but if there is no entry in the table for
* a particular code,then the original code is sent to the printer.
*
* The entries must be arranged in ascending order of Atari input
* code. The table is NULL terminated.
*
* This table assumes that the HP DeskJet printer is set in
* PC8 Character Set (Switches A1 to A4 down)

0                                * NULL: print a space
* the up arrow code will set the printer for 14 pt. Helvitica

X
XCPBOOT.TOS
X==========
X
Xobjective
X---------
XThis program is designed to copy an executable boot sector from a disk of
Xone type of format to that of an other.
X
Xwhy
X---
XThe reason for this is that I wanted to make copies of TOS 1.4 Developer's
XRelease and place them on double sided disks. Well TOS 1.4 comes on a single
Xsided disk and Atari did not provided a program to modify a boot sector with
Xthe TOS loader. The only possible way to make copies was with GEM's disk to
Xdisk copy, which ment that I could only make single sided copies. I then tried
Xusing MEMFIL14.ACC to read the boot sector from the TOS disk to that of a
Xdouble sided disk. ** Smooth move Ex-lax **!!  I had forgotten that certain
Xbits of info like number of tracks and sides, and the serial number, would be
Xdifferent on the two disks. So I ended up trashing a disk and all the info on
Xit.
X
Xwhat
X----
XBasically all CPBOOT does is to read both the source and target boot sectors
Xfrom respective disks, copies from the source the branch code, filler, and
Xthe boot sector code to the target sector. Then a call to Protobt() is made
Xin order to adjust the checksum for an executable boot sector, which is then
Xwritten back to the target disk. See CPBOOT.C.
X
Xhow
X---
XJust execute the program CPBOOT.TOS and follow the prompts. All work is done
Xon A drive so disk swapping will be necessary.
X
XDisclaimer
X----------
XI do not take responsibilty for damage caused by careless use of this program.
XMake sure that you follow the prompts, write tabs are up on disks you want to
Xprotect and that you have backups of everything. This program was a one day
Xquick utility. You can modify the source for more checks like: does the target
Xalready have a boot sector, have the disks actually been swapped, prompts
Xto select A: or B:, etc.
X
XEnvironment
X-----------
XMega ST2 with colour screen.
XBDT's GEMCSH & MAKE
```

Subject: v02i033: fplib10 -- Floating point routines for Sozobon C
Keywords: shar, C
Message-ID: <6732@saturn.ucsc.edu>
Date: 19 Mar 89 22:19:54 GMT
Sender: usenet@saturn.ucsc.edu
Lines: 712
Approved: koreth@ssyx.ucsc.edu

Submitted-by: brooks@csss-a.prime.com (David Brooks)
Posting-number: Volume 2, Issue 33
Archive-name: fplib10

[These are the sources to some floating-point library routines for Sozobon C.
 Apparently this is not the complete floating point library; the whole thing,
 in binary-only form, has been posted to the binaries group. -sg]

X        FLOATING POINT LIBRARY FOR SOZOBON C
X
X        Rev 1.0 -- prepared March 6, 1989
X
XThe files contained in this archive are an initial release of some
Xfloating point functions for Sozobon C.  We provide:
X
X    sqrt     exp      fabs
X    sin      log      ldexp
X    cos      log10         frexp
X    tan      pow      atof
X    atan     ceil
X    atan2         floor         math.h
X    asin     modf
X    acos     fmod
X
XThese are available in source.  There is also a new LIBM.A that has the
Xnew routines included (and the other routines re-arranged to remove the
Xneed to scan the library twice).
X
XThese routines may be used without restriction, but I retain the copyright
Xon them, and the Only True Upgrades will be those I make.  If you have any
Ximprovements, please send them to me.

Archive-name: prtset

[Ha! After weeks of trying, we've beaten you, BITNET! I finally got this
 intact and unmangled! Hahahhahahahahahahahaha.... Oh, sorry. -sg]

This is a small utility, meant mostly for shell scripts, but also for
an interactive use, which main purpose is to send all kind of weird
initialization codes to a printer. For example, when I am printing
.dvi files produced by TeX I am using the following two Gulam aliases,
which include some of MY printer magic, initialize system and printer
properly and restore printer to a sane (more or less) state after dvi
driver is finished.

```
dvi  prtset -s -h1b\8 ; dvc
dvc  pushd d:\texbin ; gem dvi.prg ; prtset -c -h1b401b\M1b\90d ; popd
```

I am using command 'dvi' to start my previewer, with printer off, or to
print on a single-sheet paper, and command 'dvc' to print on a
continous one. The other role of a prtset program is to set and check
proper configuration codes in situation when keeping around in memory
fat control.acc is not exactly what you would really want to do. When
printer is not on line 'prtset' just returns. It is written in
assembler, since I wanted it to be really small. I bet that you will
find also some other ways to use it.

   Enjoy,

   Michal Jaegermann

X
XPRTSET   ST USER MANUAL   PRTSET
X
X
XNAME
X   prtset - a program to set, change and display system printer
X   information and to send printer control codes
X
XSYNOPSIS
X   prtset [-c][-o][-s][-n<infocode>][-h<printcode>]
X
XDESCRIPTION
X   Prtset is a small program for a control of printing by mody-
X   fying a system printer information and sending printer codes
X   to your printer. It is meant mostly for situations in which
X   you have better uses for memory then keeping around a bulky
X   accesory. It can be used interactively, but the best place
X   for it is probably in shell scripts and command aliases.
X   Contrary to what you may think some programs do care how the
X   printer information was set.
X
X   The program checks if an printing device is on line. If it
X   is not, then an attempt to send something to the printer will
X   be silently skipped, and prtset will return, possibly
X   performing other requested actions.
X
XOPTIONS
X   The following are valid command-line options:
X
X   -n<infocode> No space between flag and code allowed.
X   Set printer information accordingly to infocode.
X   An infocode is a two-digit hex number with a bit
X   pattern set with a help of the following table:
X
X   bit   reset   set
X   --------------------------------
X   0   dot-matrix   daisy-wheel
X   1   b/w   colour
X   2   1240 dots/l   960 dots/l
X   3   draft   final
X   4   parallel   serial
X   5   continuous   single-sheet
X   6-15   reserved
X
X   -o   Show an old configuration. An output is a string
X   of 0's and 1's corresponding to reset and set bits
X   in a system printer information.
X
X   -c   Switch to printing on countinuous paper
X
X   -s   Switch to printing on single-sheet paper
X

```
X     -h<printcode>     Send to the printer a string of characters
X             defined by printcode. Characters in printcode are
X         represented either as their two-digit hexadecimal
X         codes, in either case, or literally as themselves, if
X         preceded by an escape charater '\'.  Any non-escaped
X         character, which is not a hexadecimal digit, will ter-
X         minate printcode.  Remaining non-white space characters
X         will be skipped.
X
XEXAMPLE
X    Configure a printer to Epson in NLQ mode on RS-232 port printing
X    on a fan-fold paper and set right print margin to 65 characters
X    (your control sequence may vary, check your printer manual).
X
X             prtset -n1c -h1b\Q410d
X
X    Display old printer configuration and switch to printing on
X    a single sheet paper
X
X         prtset -o -s
X
XAUTHOR
X     prtset was written by Michal Jaegermann, September 1988.
X
XBUGS
X     A command line is processed sequentially from left to right.
X     Therefore the following will work:
X
X             prtset -o -n2a -o -n1c -o -n00 -o
X
X     displaying printer configuration four times.  The same applies
X     to all other options.  This may be construed as a bug, or as
X     a feature - depending on a state of your mind.
X
X     Due to a well-know brain damage in a desktop the following,
X     executed from a command window,
X
X             prtset -h\t\e\s\t0d0a
X
X     will print 'TEST', instead of 'test'.  Use a shell which will
X     leave your command line alone, or replace escaped lower case
X     characters with corresponding hexadecimal codes.

Submitted-by: ntomczak@ualtavm.bitnet (Michal Jaegermann)
Posting-number: Volume 2, Issue 35
Archive-name: hexify

[Uuencode is much more efficient, but you can use this to send binaries
 across troublesome networks, such as BITNET (sometimes). -sg]

Here are two C programs which I used to perform a conversion to hex
and back. Binary restorer is smart enough to find a "BEGIN" line and
create file name. Both programs will compile with Sozobon C and dLibs
library (and many other compilers, I bet). [SunOS 4.0's, for one... -sg]

```
#!/bin/sh

[I'm still not too sure why this is needed, but what the heck. -sg]

The TeX system comes with a 'relatively' generic base of programs written
in Web that operate on some real or imaginary computer.  To compile these
programs for your system, you find an appropriate 'changefile' that describes
the system dependecies for your machine and include it into make.  This is
just the way god-emperor Knuth decided to do it.  It truly is a tangled
web that he has weaved.  ;-)

Anyway, anyone who wants to build a version of BibTeX, Tangle, and Weave
can get the original from the standard TeX archives at score and then
include their changefile and compile with their favorite Pascal compiler.
OR, they can wait until someone does the web2c conversion and creates
the appropriate changes there.  This seemed to be the quickest way
to get these programs to those who needed them.

#!/bin/sh
# shar:  Shell Archiver  (v1.22)
#
#    Run the following text with /bin/sh to create:
#      bibtex
#      tangle
#      weave
#
sed 's/^X//' << 'SHAR_EOF' > bibtex &&
XBibTeX change file for the Atari ST
XAuthor: Nico Poppelier.

XDate  : December 27, 1988.
X
XSince the Prospero Pascal compiler strictly adheres to the
XISO Pascal standard (level 0), all occurrences of ':0' or ': 0'
Xin write and writeln statements have to be replaced by
X':1' and ': 1', respectively.
X(This was reported to Oren Patashnik, see TeXhax of Dec 88).

XTANGLE change file for the Atari ST
XAuthor: Nico Poppelier.
XDate  : December 30, 1988.
X
XDue to an error in the Prospero Pascal compiler the control variable
Xof the FOR loops in sections 138, 182, and 184 are judged 'insecure',
Xi.e., it looks as if they are modified by a routine.
XTo avoid this 'error' a new loop variable k is introduced.

Submitted-by: koreth@ssyx.ucsc.edu (Steven Grimm)
Posting-number: Volume 2, Info 1
Archive-name: intro

This is the first of two introductory articles about comp.sources.atari.st.
This one describes how to submit source to the newsgroup, where the
archive sites are, and how to contact them.  The companion article lists
all previously-published sources.
```

I am always looking for suggestions on how to improve the usefulness
of the newsgroup, and can be contacted as listed below.

-- Steven Grimm

Subject: Submitting source for publication

Items intended for posting or queries and problem notes should be sent to
atari-sources@ssyx.ucsc.edu. If you are on a UUCP-only site, you can send
them to ucbvax!ssyx!atari-sources.

If you want verification of arrival, so say in a cover note, or at the
beginning of your submission, if it is small. I try to verify that a
program works, and if I can't get it to work, I may hold up posting it
for a couple of days. Please note that, except in rare cases, source
without documentation will not be published. The backlog from receipt
to posting varies from one to four weeks depending mostly on the set
of submissions currently in my queue.

I prefer that you submit sources and binaries separately, as it's a
pain to separate them, and such submissions are invariably placed on
the back burner. Sources should be submitted in "shar" format unless
you don't have access to a shar program, in which case "arc" is all
right.

Please inform me of any special system requirements, and what development
environment was used, so that I can properly test your submission.

Subject: The structure of comp.sources.atari.st articles

Each posting in comp.sources.atari.st is called an "issue"; there are
roughly 100 issues to a volume. The division is arbitrary and may vary.
There are two types of articles in comp.sources.atari.st: sources and
"information postings." They can be distinguished by the subject line:

  Subject: v01INF3: Index for Volume 1 and other info

This first word in the title identifies this as the third info posting of
volume one. Similarly, the subject line shown below:

  Subject: v01i081: tossrc -- Source code to TOS

identifies this as the 81st source article in Volume 1. Large sources are
broken up into smaller pieces, and have subject lines that look like
this:

  Subject: v01i082: VMS clone in ST-LOGO, Part03/08

Certain information about the system configuration required to use the program is given on the keywords line.

```
  Keywords: MWC, Megamax, 1meg, high
```

This means that the program compiles with Mark Williams or Megamax C, requires at least one meg of RAM and only runs in high resolution. Following is a list of keywords; new ones may be added as needed. They are mostly self-explanatory.

```
  Alcyon  - Alcyon C (included with Atari developer's kit)
  MWC         - Mark Williams C
  Megamax - Megamax C
  Laser       - Laser C
  Lattice - Lattice C
  C       - Any C compiler
  OSI         - OSI Personal Pascal
  BASIC       - ST BASIC (this is not a joke!)
  uuencode    - program is uuencoded (uudecode required to unpack)
  arc         - program is archived (arc required to unpack)
  high        - high resolution
  medium  - medium resolution
  low         - low resolution
  1meg        - needs 1 meg of RAM
```

The first few lines of an article are auxiliary headers that look like this:

```
  Submitted-by: david@bdt.UUCP (David Beckmeyer)
  Posting-number: Volume 1, Issue 80
  Archive-name: micro-rtx
```

The "Submitted by" is the author of the program. If you have comments about the sources published in comp.sources.atari.st this is the person to contact. When possible, this address is in domain form, otherwise it is a UUCP bang path relative to some major (backbone) site.

The second line repeats the volume/issue information for the aide of notes sites and automatic archiving programs.

The Archive-name is the "official" name of this source in the archive. Large postings will have names that look like this:

```
Archive-name: desktop/part01
```

Please try to use this name when requesting that sources be mailed to you. Also, note that the "part number" given in the title, and the archive name given in the auxiliary header need not be identical.

Since most archive sites run UNIX, articles are given UNIX-style filenames rather than ST-style filenames. I do try to limit filenames to eight characters whenever possible, though.

Subject: Reporting and tracking bugs and patches to postings

Most of the time, bugs and updates will be posted to comp.sys.atari.st.
Sometimes, "official" updates from the author will be posted submitted to
comp.sources.atari.st so that they are archived with the sources.

Since there is no easy way to apply source code patches on the ST, changes
to a program often result in a whole new version being posted.

To report bugs, contact the person listed in the Submitted-to header.
Often there is a contact address in a README file, too. I do not maintain
the sources I moderate, so don't send your bug reports to me.

Subject: Accessing the archives

At this time, there is only one site known to be keeping an archive
of comp.sources.atari.st. If you are making an archive available to
the public, or would like to, please contact me.

Subject: Listing of archive sites in no particular order

1. Site ssyx is running an archive server, which automatically answers
   mail requests. Send mail to archive-server@ssyx.ucsc.edu with the
   word "help" in the message body for more information. Both the sources
   and binaries groups are archived on ssyx.

Submitted-by: ravi@mcnc.org (Ravi Subrahmanyan)
Posting-number: Volume 2, Issue 39
Archive-name: which

Here's a trivial utility for the ST: basically the same as "which"
under unix.

```
#!/bin/sh
# shar:  Shell Archiver  (v1.22)
#
#    Run the following text with /bin/sh to create:
#      README
#      WHICH.C
#
sed 's/^X//' << 'SHAR_EOF' > README &&
XThis is an ST adaptation of a "which" program somone posted to
Xnet.sources many years ago to replace the agonisingly slow
XBSD "which" script with a program.  I've used  it on our un*x
Xsystem for years, and finally decided I couldn't do without
Xit on the ST any longer..  Anyway, here it is (with source,
Xits trivial enough.)  To use it just say
X
X% which haha
X
Xand it'll add in the ".prg" or ".tos" or ".ttp" while checking for the file.
X(it'll look for all three.)  It works with the Mark Williams C "msh" PATH,
Xbut you can easily modify it for your favourite shell, just change the comma
Xin the #define for DELIMETERat the top to whatever the delimeter is for
Xthe PATH in your shell.

Submitted-by: radoslav@kuling.docs.uu.se (Radoslav Bogdanovic)
Posting-number: Volume 2, Issue 40
Archive-name: atime89

This is the sources for the AUTO - TIMESET program which was posted to
the comp.binaries.atari.st.

---------------------- CUT HERE ----------------------------------------

: This is a shar archive.  Extract with sh, not csh.
: This archive ends with exit, so do not worry about trailing junk.
echo 'Extracting a_time89.doc'
sed 's/^X//' > a_time89.doc << '+ END-OF-FILE a_time89.doc'
X
X                    AUTO - TIMESET Version 1.0
X                 (c) by Radoslav Bogdanovic / RadoSoft
X                            17 may, 1989
X
X                For Microdeal/Michtron Internal Clock Card
X                                  and
X                Other Clock Cards working on the keyboard
X                processor for time & date maintenance.
X
```

```
X    This program works from your AUTO folder of your floppydisk or harddisk
X    and also takes over the function of the supplied AUTOTIME.PRG supplied
X    with the Microdeal/Michtron Clock Card.
X
X    The need for this program arose after I had installed the Clock Card
X    and then suddenly noticed that the clock was zeroed by some other program
X    and that I suddenly had a lot of files with wrong time and date stamp.
X    To prevent this I realised that the only way was to write a program that
X    would check if the date was somehow wrong. This is performed by checking
X    if the IKBD setting of the year is different of the xx year in the file
X    name of A_TIMExx.PRG. This mean that you only need to rename the program
X    once every year to get it to work properly.
X
X    This program was compiled with Sozobon C compiler and the complete
X    source code is supplied.
X
X    This program may freely be distributed.
X
X    I can be reached at the following address for bug reports and others:

comp.sources.atari.st: Volume 0, Issue 51
Archive-name: du.c

-+=+-

[Editor's Note]
     this was a simple, elegant program until i got my hacking little hands on it. Anyway it now supports the -s flag and directory names as arguements. If you don't have the man entry for du, this program reports disk usage for a directory and it's subdirectories (if any). The -s flag suppresses reporting subdirectories. The checksum is:

bytes =   3428(3584)   cksm = 666   du.c

-+=+-

Here's a submission to comp.sources.atari.st. Use it in good health.

```
#include <stdio.h>
#include <osbind.h>

/*
** DU.C

Posting-number: Volume 1, Info 1
Archive-name: intro

This is the first of two introductory articles about comp.sources.atari.st.
This one describes how to submit source to the newsgroup, where the
archive sites are, and how to contact them.  The companion articles lists
all previously-published sources.

I am always looking for suggestions on how to improve the usefulness
of the newsgroup, and can be contacted as listed below.
```

-- Steven Grimm

Subject: Submitting source for publication

Items intended for posting or queries and problem notes should be sent to atari-sources@ssyx.ucsc.edu. If you are on a UUCP-only site, you can send them to ucbvax!ssyx!atari-sources.

If you want verification of arrival, so say in a cover note, or at the beginning of your submission, if it is small. I try to verify that a program works, and if I can't get it to work, I may hold up posting it for a couple of days. Please note that, except in rare cases, source without documentation will not be published. The backlog from receipt to posting varies from one to four weeks depending mostly on the set of submissions currently in my queue.

Please inform me of any special system requirements, and what development environment was used, so that I can properly test your submission.

Subject: The structure of comp.sources.atari.st articles

Each posting in comp.sources.atari.st is called an "issue"; there are roughly 100 issues to a volume. The division is arbitrary and may vary. There are two types of articles in comp.sources.atari.st: sources and "information postings." They can be distinguished by the subject line:

  Subject: v01INF3: Index for Volume 1 and other info

This first word in the title identifies this as the third info posting of volume one. Similarly, the subject line shown below:

  Subject: v01i081: Public Domain Resource Construction Set

identifies this as the 81st source article in Volume 1. Large sources are broken up into smaller pieces, and have subject lines that look like this:

  Subject: v01i082: VMS clone in ST-BASIC, Part03/08

Certain information about the system configuration required to use the program is given on the keywords line.

  Keywords: MWC, Megamax, 1meg, high

This means that the program compiles with Mark Williams or Megamax C, requires at least one meg of RAM and only runs in high resolution. Following is a list of keywords; new ones may be added as needed. They are mostly self-explanatory.

```
  Alcyon  - Alcyon C (included with Atari developer's kit)
  MWC         - Mark Williams C
  Megamax - Megamax C
  Laser       - Laser C
  Lattice - Lattice C
  OSI         - OSI Personal Pascal
  BASIC       - ST BASIC (this is not a joke!)
  uuencode    - program is uuencoded (uudecode required to unpack)
  arc         - program is archived (arc required to unpack)
  high        - high resolution
  medium  - medium resolution
  low         - low resolution
  1meg        - needs 1 meg of RAM
```

The first few lines of an article are auxiliary headers that look like this:

```
  Submitted-by: david@bdt.UUCP (David Beckmeyer)
  Posting-number: Volume 1, Issue 80
  Archive-name: micro-rtx
```

The "Submitted by" is the author of the program. If you have comments about the sources published in comp.sources.atari.st this is the person to contact. When possible, this address is in domain form, otherwise it is a UUCP bang path relative to some major (backbone) site.

The second line repeats the volume/issue information for the aide of notes sites and automatic archiving programs.

The Archive-name is the "official" name of this source in the archive. Large postings will have names that look like this:

```
Archive-name: desktop/part01
```

Please try to use this name when requesting that sources be mailed to you. Also, note that the "part number" given in the title, and the archive name given in the auxiliary header need not be identical.

Since most archive sites run UNIX, articles are given UNIX-style filenames rather than ST-style filenames.

Subject: Reporting and tracking bugs and patches to postings

Most of the time, bugs and updates will be posted to comp.sys.atari.st. Sometimes, "official" updates from the author will be posted submitted to comp.sources.atari.st so that they are archived with the sources.

Since there is no easy way to apply source code patches on the ST, changes to a program often result in a whole new version being posted.

To report bugs, contact the person listed in the Submitted-to header.

Often there is a contact address in a README file, too. I do not maintain
the sources I moderate, so don't send your bug reports to me.

Subject: Accessing the archives

At this time, there is only one site known to be keeping an archive
of comp.sources.atari.st. If you are making an archive available to
the public, or would like to, please contact me.

Subject: Listing of archive sites in no particular order

1. Site killer has a full archive available for anonymous UUCP. For
   information on accessing it, send mail to Bill Wisner:
   {ames,codas,ihnp4,mit-eddie}!killer!wisner.

[This is rather timely, as discussions about just this sort of program have
 been going on in comp.sys.atari.st. It should work with any C compiler,
 but has only been tested with Laser and Megamax C. -sg]

```
/*--------------------------------------------------------------------
| Bootcopy version 1.0:   In the Public Domain
|        Greg Anderson
|
| This program copies everything inside the folder "AUTOCOPY" onto
| the Ramdisk on powerup.  If "AUTOCOPY" contains folders, these
| folders are created on the Ramdisk, and their contents are also
| copied.  There is no limit to the depth of folders that can be
| placed inside "AUTOCOPY".
|
| Usage:
|        Putting Bootcopy into the AUTO folder:
|
| 1. If you already have an AUTO folder on your disk, save the files
|    inside it somewhere and delete it.
| 2. Create (or recreate) your AUTO folder.
| 3. Real-time-clock setting programs (such as CLKSET for DeskCart)
|    may be copied to the AUTO folder if desired.
| 4. Copy your RamDisk to the Auto folder.  Desk accessory RamDisks
|    are not suitable, as the RamDisk MUST be installed before
|    Bootcopy runs.  VEGEMATIC (MEGEMATIC.PRG) is the recommended
|    RamDisk.  Make sure that your RamDisk is the drive with the
|    highest letter, or Bootcopy will copy its files to the wrong
|    drive.
| 5. Copy BOOTCOPY.PRG to the Auto folder
| 6. Copy any other programs you wish to place in the Auto folder.
|
|        Setting up the AUTOCOPY folder:
|
| 1. Create a folder called AUTOCOPY.  It may be placed in one of
|    two locations:  on the root, or inside the AUTO folder.
| 2. Copy any files you wish to be moved to the RamDisk on powerup
```

```
|    to the AUTOCOPY folder.
|
| That's all there is to it.  The author can be reached as follows:
|

[Lots of STers seem to have trouble reading the joystick ports, which is much
 more painful on the ST than on the 8-bit.  These routines should help make
 it easier.  Note that these are just some routines, and not a complete
 program. -sg]

/*-----------------------------------------------------------------------
| Stick.c:  Joystick interupt service routine
|
| Placed in the public domain March 1988 by Greg Anderson.
|
|      The joystick demo by Steve Jankowski was instrumental to
|                  the creation of these routines.
|
|   Many thanks to Steven Grimm for providing essential information
|               and the aforementioned joystick demo.
|
|#######################################################################
| THESE ROUTINES ONLY WORK UNDER LASER C!  THEY MUST BE MODIFIED FOR
| OTHER C COMPILERS, _INCLUDING_ MEGAMAX C VERSION 1.xx!
|
| MegaMax instructions:  A4 must be saved somewhere so that it is
|     available durring the isr.  Then, the isr can access joyinf
|     with "lea joyinf(A4),A1" instead of "lea joyinf,A1".
|#######################################################################
|
|     This package sets up an interupt to read the joystick on the
| ST.  The joystick is read via the ikbd--the intelligent keyboard
| interface chip.  The ikbd can be placed into "joystick-reading
```

```
| mode" by sending an appropriate command with Ikbdws().  This has
| two effects:  first, the mouse is disabled.  Second, the ikbd will
| be prompted to send a three-byte packet every time one of the
| joysticks changes states.  The packet is as follows:
|
|     [Stick #]  [State of Stick 0]  [State of Stick 1]
|
|     The first byte is $FE if stick 0 changed, or $FF if stick 1
| changed.  These routines ignore the first byte.
|     The next two bytes contain the states of sticks 0 and 1.
| There values will be the sum of:
|
|                  +1    (+128)
|                   |
|            +4 ---< >--- +8
|                   |
|                  +2
|
|     Add the apropriate value if the contact is down.  For example,
| if stick 0 is NW and the trigger has not been pressed, its
| current state will be 1 + 4 = 5.
|
|     These packets are sent to a routine pointed to by "joyvec".
| Joyvec is part of the structure returned by Kbdvbase().  Joyvec
| can be changed to point to an interupt service routine (isr) of
| our devising.  If this is done, the isr will find that A0 points
| to the first byte of the the packet sent by the ikbd.  The isr
| must be very short (less than 1ms exicution time).  Atari's docs
| of Kbdvbase indicate that a copy of the pointer to the packet is
| also deposited on the stack; however, this does not appear to be
| the case.
|
| Using these routines:
|
| Call stick_init() to set up the joystick isr and place the ikbd
|    into joystick send mode.  This will also disable the mouse.
|
| stick_exit() will return the ikbd to mouse send mode.  Your
|    program should do this before exiting.
|
|    Once the initialize routine has been called, the following
| commands are available:
|
| _stick(n):  Return the state of stick N.  (See above chart)
| stick(n) :  Return the direction of stick N.  (Minus the trigger)
| trig(n)  :  Return the state of the trigger on stick N.
| hstick(n):  Return the horizontal position of stick N.  (-1 to +1)
| vstick(n):  Return the vertical position of stick N.
|

Here is a very simple little utility.
If you want to recycle a previously-used diskette, you can either
delete all the files and folders on it (slow) or reformat it (also
slow).  Or you can use this program, BLANK.TOS.  It zeros out the
FATs (excluding the first 3 bytes) and the root directory.  The
disk then looks just like a freshly formatted one to TOS.
You specify the drive letter, and BLANK will handle TOS or MS-DOS
disks of all sizes and formats.

The source (Laser C) follows.  It should compile with any ST C
compiler, just make sure 'WORD' is defined to 'int' or 'short', whatever
is 16 bits long.

- Moshe Braner

~~~~~~~~~~~~~~~ cut here ~~~~~~~~~~~~~~~~
/*
 *   BLANK
 *
 *   A program to blank out a floppy disk.
 *   The disk must have been formatted before.
 *   Much faster than reformatting or even
 *   deleting all that's on the disk by files.
```

```

 * Floppy Disk Cache (Atari ST)
 *
 * Copyright 1988, Eric Gisin <egisin@UWaterloo.CA>
 * this program may be copied as long as this copyright notice is retained.
 * the author will not be liable for any damages resulting from the use of this
program.
 *
 * Usage: cache [drive][size]
 *   can be loaded twice to handle two drives.
 *
 * The cache is based on paging and page replacement techniques
 * used in virtual memory systems. The replacement algorithm is
 * similiar to "not frequently used" (NFU).
 *
 * each sector of the disk has a (struct) Cache element
 * that contains a pointer to a cache buffer,
 * and an "average usage" value.  The average is a combination
 * of long term usage and short term usage (somethink like 4bsd's load avg).
 * there are also averages for total IO, read, write, hits, and reclaims.
 * an average is increased for each reference (read/write),
 * and all averages are decreased (by a percentage) every 100 accesses.
 * the reference function is:    avg += A_INC; A_INC = 16;
 * the update function is:  avg -= 1/8*avg;
 * for these parameters, the total avg will tend between 12800 and 14400.

              Floppy Disk Cache

     What is a disk cache?
A disk cache is resident program that speeds up disk IO
by keeping a copy of recently used sectors of the disk
in RAM memory.  It is similar to a RAM disk but has the
advantage that files are always up-to-date on the disk.
You can't lose files like a RAM disk does when the system crashes.

This cache will typically eliminate from 50-85% of disk IO if enough
cached sectors are installed. There is a slight CPU
overhead in copying sectors to the cache after disk IO.

     Installation
The programs cache.ttp and cstat.ttp should be placed
in your directory for executable files, usually \bin.
cache.ttp should be run from a shell startup file;
for example gulam.g under Gulam or GemBoot's startup file.
The first argument to "cache" is the size of the cache in K-bytes,
which defaults to 50K.  The size can be preceeded by a drive letter.
Run "cache" twice if you need to cache two drives.
If you install cache.ttp as \auto\cache.prg
there is no way to set the drive or cache size without modifing the source.

     Operation
The cache clears automatically whenever you change disks.
Make sure all your disks have been formatted correctly with unique
serial numbers. An early version of twister and any bit-image
```

disk copy program will not generate unique serial numbers.
An easy way to check for unique serial numbers is:
list the root directory, switch disks, list the root directory.
If the directory lists are identical then the serial numbers may be the same.
You will probably trash disks even without a disk cache
when you have non-unique serial numbers.

The utility "cstat" will print some statistics averaged over
the last 1000 (approx.) sectors of IO.

     Other Hints
Using a "fast" formatter like DC Format will speed up disk IO further.
You can also turn off write verify with DC Format or pokew in Gulam,
but there is some risk of losing files then.
It also helps to create all directories before anything else
is placed on a new disk, this speeds up file creation and deletion.

     Compilation
This program is written completly in C for readability and portablity.
The cache program should be compiled with the dLibs library or MWC.
It requires the _base, _break, and _STKSIZ variables dLibs implements.
Non-standard compilers may require a "define short int".
Please indicate in the source and object when you make non-trivial changes.

     Possible Extensions
Modify it for multiple hard disk partitions. This is non-trivial.
The current algorithm assumes sectors can be accessed through
cache[sector]. The cache array would be 160K bytes for a 20M byte drive,
and is scanned sequentially in a couple of places.

Submitted-by: egisin@watmath.waterloo.edu (Eric Gisin)
Posting-number: Volume 1, Issue 33
Archive-name: vdit

This is a partial PD VDI interface with support for loading GDOS fonts.
See the file "readme" at the beginning of the shell archive.
A set of PD GDOS fonts has been posted to comp.binaries.atari.st.

[I don't know which C compiler was used to develop this program, but the
 code looks fairly non-compiler-specific. -sg]

```
# This is a shell archive.  Remove anything before this line,
# then unpack it by saving it in a file and typing "sh file".

This package contains a partial public domain VDI interface.
It includes a working interface to the undocumented
VDI "load_fonts" and "unload_fonts" functions,
which allow you to use other fixed and proportional fonts with GEM's VDI.
See vdit.c for documentation and an example.
Most of vdi.h/vdi.c is untested, except for the functions
used by vdit.c and by my VT200 emulator.
If you make any fixes or enhancements to the VDI I'd like to see them.
I have also posted a public domain fixed width font family
suitable for use with terminal emulators to comp.binaries.atari.st.

vdi.h:        structure and macro definitions for VDI
vdi.c:        interface functions for VDI
gfont.h: definition of a GDOS font
loadfont.c:   load GDOS fonts from disk
vdit.c:       a simple program to load fonts and display them

/* FLIP HISTORY & MANUAL */

/* HISTORY:
 *=========
 *   2.6b tells when copies an executable boot to detect virii
 *   2.6a bug de 'r' repaired
 *        No checksum done if no previous checksum
 *        option 's' for single instead of double (double=default)
 * v 2.6  27 fevrier 88
 *   2.5c re-designing of command parsing
 *    formats disk ('f' command)
 *    randomization of serial # at each copy
 *   2.5b t can override disk
 *    ESC aborts without confirm
 *   2.5a no ESC to another disk, BS!
 *    aborts on key even in format
 *    man in another C file
 * v 2.5  released
 *  2.4.5 write-protect detected
 *  2.4.3 option v to verify source only
 *    multipass copies possible
 *  2.4.2 all sects# outputted on any kind of error.
 *        twister modified to accept starttrack parameter
 *    track_map to know what to copy
 *    t option to specify track
 *    r takes options fvV
 *  2.4.1 i for interactive: default no stop
 *    V verify after format (case-sensitive options)
 *    bug of verify reading into main buffer repaired
 * v 2.4: Jan 15 88
 *  2.3.2 If esc on insert abort
 *    track_read first
 *    no more skip opt
 *    # of sect printed
 *  2.3.1 Drive B presence is really tested
 * v 2.3: Dec 28 87
 *  2.2.3 comparisons were not done!!! -- repaired
 *    copy by 3 sectors
 *        stops if copy sector only by 1
 *  2.2.2 bug de a1a1 repare
 *  2.2.1 no verify by default
 *    r for re-copy
 * v 2.2: Dec 19 87
 *  2.1.1 prints buffer size on start
 *    sector_read done 4 times with comparison!
 *    RETURN repeats last command
 * v 2.1: Nov 28 87
 *  2.0.1 retrys in writes and verify work now.
 *    verify there is a drive B before copying
 * v 2.0: Nov 22 87
```

```
 *  1.6.3 verify is another pass
 *  1.6.2 format does not verify anymore
 *     format outputs a char
 *  1.6.1 uses TWISTER's code mmtwst.c to format
 * v 1.6: Nov 11 87
 *  1.5.4 abort on ESC
 *        option "2" for 2-sided.
 *  1.5.3 abort on key with confirm
 *  1.5.2 track, sectors begin at 1 instead of 0
 *        retrys on writes retry format-write-verify loop
 *     on write errors, ESC to go to another disk
 *  1.5.1 port to megamax
 *     uses all memory
 * v 1.5: more checking of entry syntax.
 *        on-line help
 *        fills bad sectors with 0s before writing
 *     more sensible memory allocation
 *     s option for auto skip
 * v 1.4: one automatic retry without prompting. If skips, copies good
 *     sectors anyway.
 * v 1.3: when error on a track, asks for retrys, which are done sector
 *        by sector.
 * v 1.2: when double sided, copy the two sides
 * v 1.1: whole side in memory for one drive use.
 * v 1.0: original one in mark williams. quick and really dirty.

Flip is a small copier that I wrote for my personal use to:

- use the back of SS disks

- try to save data from damaged disks (getting frustrated with the abort
  message of DCFORMAT)
```

Since I and my friends are using it all the time, it might be of use to some
netlanders. As it was developed for my own use, it is not under GEM.
It is in no way as great a program as is GULAM or UNITERM

It is completly public domain, files are: (MEGAMAX C v1.1)

binaries:
     flip_26b.tos   the executable

sources:
     makefile
     flip.c   main code
     man.c   manual & history
     twst.c   formatter in in-line assembly, in fact TWISTER code
               slightly modified (MEGAMAX v1.1)
```

; Primitives to read/write 1770 controller chip (DISKCTL register).
;
; The 1770 can't keep up with full-tilt CPU accesses, so
; we have to surround reads and writes with delay loops.
; This is not really as slow as it sounds.
;
wdiskct6:                             ; write D6 to diskctl
        bsr     rwdelay               ;       delay
        move.w  D6,diskctl            ;       write it
        bra     rwdelay               ;       delay and return

wdiskctl:                             ; write D7 to diskctl
        bsr     rwdelay               ;       delay
        move.w  D7,diskctl            ;       write it
        bra     rwdelay               ;       delay and return

rdiskct7:                             ; read diskctl into D7
        bsr     rwdelay               ;       delay
        move.w  diskctl,D7            ;       read it
```

```
        bra     rwdelay                 ;       delay and return

rdiskctl:                               ; read diskctl into D0
        bsr     rwdelay                 ;       delay
        move.w  diskctl,D0              ;       read it
; And here's the delay loop:
rwdelay:
        move    SR,-(A7)                ; save flags
        move.w  D7,-(A7)                ; save counter register
        move.w  #0x20,D7                ; 0x20 seems about right...
rwdly1: dbf     D7,rwdly1               ; busy-loop: give 1770 time to settle
        move.w  (A7)+,D7                ; restore register, flags, and return
        move    (A7)+,SR

Archive-name: rzsz/part01

[This is the UNIX end to the zmdm file transfer program in comp.binaries.
 It provides for batch transfers, among other things.  You'll probably
 only want this if you plan to use zmdm. -sg]

#!/bin/sh
# shar:  Shell Archiver  (v1.22)
#
# This is part 1 of a multipart archive
# do not concatenate these parts, unpack them in order with /bin/sh
#
#    Run the following text with /bin/sh to create:
#      Makefile
#      README
#      expandar.c
#      gz
#      minirb.1
#      minirb.c
#      rbsb.c
#      rz.1
#      rz.c
#      sz.1
#      sz.c
#      zm.c
#      zmodem.h
#
if test -r s2_seq_.tmp
then echo "Must unpack archives in sequence!"
     next=`cat s2_seq_.tmp`; echo "Please unpack part $next next"
     exit 1; fi

XNOTE::
X    Users of zmdm on the Atari ST's please see note at end of file.
X-------------------------------------------------------------------------------
XCompile instructions are located in the comments at the beginning of the rz.c
Xans sz.c files.  The main compiler flags are -DV7 for V7 and BSD systems and
X-DSVR2 for sVr2.  Other #ifdefs in the files may be activated to deal with
Xvarious types of kernel brain damage if you have a mutant system.
X
XNaturally, rz ans sz work best with comm programs that seamlessly support ZMODEM
Xcommand and file AutoDownload (PowerCOm, Pro-YAM and ZCOMM).  Ths DOS "DSZ"
Xsub-program allows ZMODEM file transfers with older programs, but it must be
Xcalled manually.  DSZ and the ZMODEM protocol description are on TeleGodzilla
Xand other bulletin boards.  They may be obtained via UUCP from site "omen", for
Xwhich a direct UUCP login and telephone number are provided below.  You may uucp
X~uucp/FILES first to determine the pathnames for the "goodies".

X
X         Case Western Reserve U 'enhancements':
X    (feed back about these enhancements to bammi@mandrill.cwru.edu)
X
XThis distribution contains some enhancements to the code as distributed
Xby Chuck Forsberg. These enhancements will only work if the proprocessor
Xsymbol 'CASE' if defined. PLEASE NOTE THAT THESE ENHANCEMENTS HAVE ONLY
XBEEN TESTED ON Unix (Vax/Sun) BSD4.X SYSTEMS. They should work on
Xother flavors of BSD, but WILL NOT WORK ON ANY OTHER FLAVORS OF UNIX
X(ie. when you compile make sure that the preprocessor symbol `CASE' is
XNOT defined, if you are not using BSD Unix).
X
XThe 'enhancements':
X
X1) When sending files with SZ, if one of the arguments is the name
Xof a directory, then all the files in that directory, and all the
Xsub-directories thereof will be sent. If you want the complete
Xpath names to be sent also, use the -f option of SZ. Also, to give
Xbetter control the  -P name switch was added. -P name prunes the
Xsubdirectory named, so that it is not included. The arguement to
X-P can be the name of a sub-directory, of the name of a file. If it
Xis the name of a sub-directory, then that branch of the file hierarcy
Xis 'pruned' and is not sent. If it the name of a file, then that
Xparticular file is not sent. For example, if you were backing up the
Xfile system of your unix system (hypothetical of course :-) to your ST,
Xand did'nt want to backup /tmp amd /etc, then you would issue the
Xfollowing command to your unix system:
X
X    sz -f -P /tmp -P /etc /
X
X    (and come back the next day!!)
X
X2) When receiving files with RZ, if the sender is sending full
Xpath names (-f option to SZ), then all directories that do not exist,
Xwill be automatically created by RZ.
X
X3) sz now allows you to send long blocks at low baud rates (<= 2400 baud).
X    try sz -l 1024 files ...
XEarlier it insisted on 256 byte blocks max at 2400 baud or less.
X
X    Any comments and/or suggestions about these enhancements should
Xbe directed to
Xusenet:      {decvax,sun}!cwruecmp!bammi jwahar r. bammi

X#ifdef CASE
X
```

```
X    /* CWRU specific extention(hack :-)
X     *   Examine each argument given to main,
X     *   If it is a directory, then expand it
X     *   to all its component files, recursively
X     *   till you bottom out.
X     *   If it is not a directory, then just pass it on.
X     *
X     *   Inputs: argc, argv
X     *   Outputs: nargc, nargv (calls MAIN(nargc, nargv))
X     *   To test: compile with -DCASE -DTEST
X     *         run with a directory as an arg
X     *   Hacker: JRB
X     *   Requirements: BSD 4.2/3 specific routines used
X     *              only tested on Vax BSD 4.3
X     *
X     *   Added -P name prune option at the suggestion of dietz@zhmti
X     *   Multiple -P's may be given on the command line.
X     *   -P name may be given anywhere on the command line. -P name
X     *   will prune the subdirectories named as arguement to -P.
X     *   ie: when the program is decending the file hierarchy it
X     *   will not visit the pruned branches.
X     *   NOTE that the option is -P and not -p
X     *         (-p is a valid sz option).
X     *   NOTE that the arguement given to -P can be the name
X     *   of a file or a directory. In case it is a file,
X     *   that file is skipped.
X     *

X.TH MINIRB 1 OMEN
X.SH NAME
Xminirb \- Bootstrap YMODEM Batch file receive
X.SH SYNOPSIS
X.B minirb
X.SH DESCRIPTION
X.I Minirb
Xreceives one or more files with YMODEM batch file transfer protocol.
```

```
X.I Minirb
Xwas developed for use as a bootstrap to simplify uploading of the longer
X.I rz
Xand
X.I sz
Xprograms contained in the
X.I rzsz1et2.sh
Xshell archive.
X.SH SEE ALSO
XYMODEM.DOC,
XProfessional-YAM manual,
Xsz(omen),
Xusq(omen),
Xundos(omen)
X.SH NOTES
XThe source file
X.I minirb.c
Xhas been ruthlessly pruned to simplify uploading without benefit of
Xany file transfer protocol.
XDo not reformat or add tabs to the source file
Xas this would complicate uploading.
X
XPlease read the uploading suggestions in the chapter
X.I "File Transfer Basics"
Xin the Professional-YAM or ZCOMM user's manual.
X
X.I Minirb
Xuses 8 bit checksum which may not be compatible with some programs
Xclaiming to support YMODEM batch transfers.
X
X.I Minirb
Xuses the
XYMODEM header
Xfile length information
Xto prevent extraneous characters.
X.I Minirb
Xdoes not delete carriage returns from uploaded files.
XIt does not delete ^Z or other padding added by some CP/M or PC-DOS
Xprograms, including the Xenix "doscp" command.
X
X.I Minirb
Xcalls stty(1) to set and reset raw tty mode.
SHAR_EOF
chmod 0600 minirb.1 || echo "restore of minirb.1 fails"
sed 's/^X//' << 'SHAR_EOF' > minirb.c &&
X/*
X * minirb.c By Chuck Forsberg Omen Technology INC
X *        "The High Reliability Communications Software"
X *
X * A bootstrap program for Unix to receive files from computers running
X *  YMODEM Batch (Professional-YAM, PowerCom, ZCOMM, etc.).
X *
X *  Minirb uses system(3) to call stty, avoiding system dependent code.
```

```
X *  Please refer to rz.c for comments, etc.

X *
X * -rev 03-10-87
X *  This file contains Unix specific stuff for setting terminal modes,
X *  very little is specific to ZMODEM or YMODEM per se (that stuff is in
X *  sz.c and rz.c).  The CRC-16 routines used by XMODEM, YMODEM, and ZMODEM
X *  are also in this file, a fast table driven macro version
X *
X *   This file is #included so the main file can set parameters such as HOWMANY.
X *   See the main files (rz.c/sz.c) for compile instructions.
X */

X *
X *   Need an unsigned type capable of holding 32 bits;
X */
Xtypedef unsigned long int UNS_32_BITS;
X
X/* First, the polynomial itself and its table of feedback terms.  The  */
X/* polynomial is                                                       */
```

```
X/* X^32+X^26+X^23+X^22+X^16+X^12+X^11+X^10+X^8+X^7+X^5+X^4+X^2+X^1+X^0 */
X/* Note that we take it "backwards" and put the highest-order term in  */
X/* the lowest-order bit.  The X^32 term is "implied"; the LSB is the   */
X/* X^31 term, etc.  The X^0 term (usually shown as "+1") results in    */
X/* the MSB being 1.                                                    */
X
X/* Note that the usual hardware shift register implementation, which   */
X/* is what we're using (we're merely optimizing it by doing eight-bit  */
X/* chunks at a time) shifts bits into the lowest-order term.  In our   */
X/* implementation, that means shifting towards the right.  Why do we   */
X/* do it this way?  Because the calculated CRC must be transmitted in  */
X/* order from highest-order term to lowest-order term.  UARTs transmit */
X/* characters in order from LSB to MSB.  By storing the CRC this way,  */
X/* we hand it to the UART in the order low-byte to high-byte; the UART */
X/* sends each low-bit to hight-bit; and the result is transmission bit */
X/* by bit from highest- to lowest-order term without requiring any bit */
X/* shuffling on our part.  Reception works similarly.                  */
X
X/* The feedback terms table consists of 256, 32-bit entries.  Notes:   */
X/*                                                                     */
X/*     The table can be generated at runtime if desired; code to do so */
X/*     is shown later.  It might not be obvious, but the feedback      */
X/*     terms simply represent the results of eight shift/xor opera-    */
X/*     tions for all combinations of data and CRC register values.     */
X/*                                                                     */

X.B rb
X.RB [\- "\ +1abqtuv" ]
X.br
X.B rz
X.RB [\- "\ 1abcqtuv" ]
X.I file
X.br
X.B gz
X.I "file ..."
X.br
X.RB [ \- ][ v ] rzCOMMAND
X.SH DESCRIPTION
XThis program uses error correcting protocol to receive
Xfiles over a serial port from a variety of programs running under
XPC-DOS, CP/M,
X.SM Unix,
Xand other operating systems.
X
XThe first form of
X.I rz
X(Receive ZMODEM)
Xreceives files with the ZMODEM batch protocol.
XIf the sending program does not support ZMODEM,
X.I rz
Xsteps down to YMODEM protocol
Xafter 50 seconds.
XThis delay can be eliminated by calling the program as
X.I rb .
X
XWhen receiving with XMODEM or YMODEM,
X.I Rz
Xaccepts either standard 128 byte sectors or
X1024 byte sectors
X(YAM
X.B -k
Xoption).
XThe user should determine when
Xthe longer block length
Xactually improves throughput without causing problems.
X
XIf extended file information (file length, etc.)
Xis received,
Xthe file length controls the number of bytes written to
Xthe output dataset (YMODEM only),
Xand the modify time and file mode
X(iff non zero)
```

```
Xare set accordingly.
X
XIf no extended file information is received,
Xslashes in the pathname are changed to underscore,
Xand any trailing period in the pathname is eliminated.
XThis conversion is useful for files received from CP/M systems.
XWith YMODEM, each file name is converted to lower case
Xunless it contains one or more lower case letters.
X
X
XThe second form of
X.I rz
Xreceives a single
X.I file
Xwith XMODEM protocol.
XThe user must supply the file name to both sending and receiving programs.
X
X.I Gz
Xis a shell script which calls
X.I sz
Xto command a Pro-YAM or compatible program to transmit the specified files.
XPathnames used with
X.I gz
Xmust be escaped if they have special significance to the Unix shell.
X.br
XEXAMPLE:
Xgz "-1 C:*.c D:*.h"
X
X
XThe third form of
X.I rz
Xis invoked as
X.B rzCOMMAND
X(with an optional leading \- as generated by login(1)).
XFor each received file,
Xrz will pipe the file to ``COMMAND filename''
Xwhere filename is the name of the transmitted file
Xwith the file contents as standard input.
X
XEach file transfer is acknowledged when COMMAND exits with 0 status.
XA non zero exit status terminates transfers.
X
XA typical use for this form is
X.I rzrmail
Xwhich calls rmail(1)
Xto post mail to the user specified by the transmitted file name.
XFor example, sending the file "caf" from a PC-DOS system to
X.I rzrmail
Xon a
X.SM Unix
Xsystem
Xwould result in the contents of the DOS file "caf" being mailed to user "caf".
X
```

```
XOn some
X.SM Unix
Xsystems, the login directory must contain a link to
XCOMMAND as login sets SHELL=rsh which disallows absolute
Xpathnames.
XIf invoked with a leading ``v'',
X.I rz
Xwill report progress to /tmp/rzlog.
XThe following entry works for
X.SM Unix
X3.0:
X.ce
Xrzrmail::5:1::/bin:/usr/local/rzrmail
XIf the SHELL environment variable includes
X.I "rsh"
Xor
X.I "rksh"
X(restricted shell),
Xrz will not accept absolute pathnames
Xor references to a parent directory,
Xwill not modify an existing file, and
Xremoves any files received in error.
X
XIf
X.B rz
Xis invoked with stdout and stderr to different datasets,
XVerbose is set to 2, causing frame by frame progress reports
Xto stderr.
XThis may be disabled with the
X.B q
Xoption.
X
X.PP
XThe meanings of the available options are:
X.PP
X.PD 0
X.TP
X.B 1
XUse file descriptor 1 for ioctls and reads (Unix only).
XBy default, file descriptor 0 is used for ioctls and reads.
XThis option allows
X.B zz
Xto be used with the
X.I Professional-YAM
X.B $
Xcommand.
X.TP
X.B a
XConvert files to
X.SM Unix
Xconventions by stripping carriage returns and all characters
Xbeginning with the first Control Z (CP/M end of file).
X.TP
```

```
X.B b
XBinary
X(tell it like it is)
Xfile transfer override.
X.TP
X.B c
XRequest 16 bit CRC.
XXMODEM file transfers default to 8 bit checksum.
XYMODEM and ZMODEM normally use 16 bit CRC.
X.TP
X.B D
XOutput file data to /dev/null; for testing.
X.TP
X.B p
X(ZMODEM) Protect: skip file if destination file exists.
X.TP
X.B q
XQuiet suppresses verbosity.
X.TP
X.B "t tim"
XChange timeout to
X.I tim
Xtenths of seconds.
X.TP
X.B v
XVerbose
Xcauses a list of file
Xnames to be appended to
X/tmp/rzlog .
XMore v's generate more output.
X.PD
X.ne 6
X.SH EXAMPLES
X.RE
X(Pro-YAM command)
X.RS
X.I <ALT-2>
X.br
XPro-YAM Command:
X.I "sz *.h *.c"
X.br
X(This automatically invokes
X.I rz
Xon the connected system.)

XYMODEM.DOC,
XIMP(CP/M),
XProfessional-YAM,
Xsz(omen),
Xusq(omen),
Xundos(omen)
```

```
X
XCompile time options required
Xfor various operating systems are described in the
Xsource file.
X.SH NOTES
XThe Unix "ulimit" parameter must be set high enough
Xto permit large file transfers.
X
XThe TTY input buffering on some systems may not allow long blocks
Xor streaming input, especially at high baud rates.
XThe Pro-YAM
X.B "zmodem l"
Xnumeric parameter may be set to a value between 64 and 1024 to limit the
Xburst length ("zmodem pl100").
X
X32 bit CRC code courtesy Gary S. Brown.
X.SH BUGS
XPathnames are restricted to 127 characters.
XIn XMODEM single file mode, the pathname given on the command line
Xis still processed as described above.
XThe ASCII option\'s CR/LF to NL translation merely deletes CR\'s;
Xundos(omen) performs a more intelligent translation.
X.SH "VMS VERSION"
XSome of the #includes with file names enclosed with angle brackets <>
Xmay need to have the angle brackets changed to "", or vice versa.
X
XThe VMS version does not set binary mode according to the incoming
Xfile type.
XNon binary file processing consists of stripping all characters beginning
Xwith CPMEOF (^Z).
X
XThe VMS version does not set the file time.
X
XAt high speeds,
XVMS sometimes loses incoming characters, resulting in retries
Xand degradation of throughput.
X
XThe mysterious
XVMS C Standard I/O Package and RMS may interact to modify
Xfile contents unexpectedly.
X
XThe VMS version does not support invocation as
X.B rzCOMMAND .
XZMODEM has not yet been implemented on the VMS version.
X.SH "ZMODEM CAPABILITIES"
X.I Rz
Xsupports incoming ZMODEM binary (-b), ASCII (-a),
Xprotect (-p),
Xand append (-+)
Xrequests, and ZMODEM command execution.
X.SH FILES
Xrz.c, rbsb.c, zm.c, zmodem.h source files.
X
```

```
X/tmp/rzlog stores debugging output generated with -vv option.
X.SH CWRU `ENHANCEMENTS'
XIf you compiled
X.I rz
Xwith the pre-processor symbol `CASE' defined, then when the
Xremote sends files with full path names (with
X.I sz -f
Xin Zmodem mode), all subdirectories that are needed to receive
Xthese files will be created, if they do not already exist. Note that
Xpathnames are always considered relative to the current directory,
Xso even if the remote sends a file with the pathname "/foo/bar", the
Xfile goes into "./foo/bar". If the directory "./foo" does not exist,
Xit will be created.
X.sp 1
XThe CWRU `enhancements' use Berkeley Unix specific code, and have been
Xtested only under BSD4.3. When making
X.I rz
Xplease make sure that you are using the appropriate flavor of Unix, before
Xdefining the pre processor symbol `CASE'.

X.SH DESCRIPTION
X.B Sz
Xuses the ZMODEM, YMODEM or XMODEM error correcting protocol to send
Xone or more files over a serial port to a variety of programs running under
XPC-DOS, CP/M, Unix, VMS, and other operating systems.
X
X
XThe first form of
X.B sz
Xsends one or more files with ZMODEM or YMODEM batch protocol.
XNormally, only the file name part of the pathname is transmitted.
XOn
X.SM Unix
Xsystems, additional information about the file is transmitted.
XIf the receiving program uses this information,
Xthe transmitted file length controls the exact number of bytes written to
```

```
Xthe output dataset,
Xand the modify time and file mode
Xare set accordingly.
X
XOutput from another program may be piped to
X.B sz
Xfor transmission by specifying the
X.B -1
Xoption and denoting standard input by "-":
X.ce
Xps -ef | sz -
XThe program output is transmitted with the filename sPID.sz
Xwhere PID is the process ID of the
X.B sz
Xprogram.
XIf the environment variable
X.B ONAME
Xis set, that is used instead.
XIn this case, the Unix command:
X.ce
XONAME=con ps -ef|sz -ay -
Xwill send a "file" to the PC-DOS console display.
XThe
X.B -y
Xoption instructs the receiver to open the file for writing unconditionally.
XThe
X.B -a
Xoption
Xcauses the receiver to convert Unix newlines to PC-DOS carriage returns
Xand linefeeds.
X
XUnix
X.B sz
Xsupports
X.B YMODEM-g
Xwith "cbreak" tty mode, XON/XOFF flow control,
Xand the interrupt character set to CAN.
X.B YMODEM-g
X(Professional-YAM
X.B g
Xoption)
Xincreases throughput over error free channels
X(direct connection, X.PC, etc.)
Xby not acknowledging each transmitted sector.
X
X
XThe second form of
X.B sz
Xuses the
X.B -X
Xflag to send a single
X.I file
Xwith
```

```
X.B XMODEM
Xor
X.B XMODEM-1k
Xprotocol.
XThe user must supply the file name to both sending and receiving programs.
X
XIff
X.B sz
Xis invoked with $SHELL set and iff that variable contains the
Xstring
X.I "rsh"
Xor
X.I "rksh"
X(restricted shell), sz operates in restricted mode.
XRestricted mode restricts pathnames to the current directory and
XPUBDIR (usually /usr/spool/uucppublic) and/or subdirectories
Xthereof.
X
X
XThe third form sends a single COMMAND to the receiver for execution.
X.B Sz
Xexits with the COMMAND return value.
XIf COMMAND includes spaces or characters special to the shell,
Xit must be quoted.
X
X
XThe fourth form sends a single COMMAND to the receiver for execution.
X.B Sz
Xexits as soon as the receiver has correctly received the command,
Xbefore it is executed.
X
X
XIf sz is invoked with stdout and stderr to different datasets,
XVerbose is set to 2, causing frame by frame progress reports
Xto stderr.
XThis may be disabled with the
X.B q
Xoption.
X.PP
XThe meanings of the available options are:
X.PP
X.PD 0
X.TP
X.B +
XInstruct the receiver to append transmitted data to an existing file
X(ZMODEM only).
X.TP
X.B 1
XUse file descriptor 1 for ioctls and reads (Unix only).
XBy default, file descriptor 0 is used.
XThis option allows
X.B sz
Xto be used with the
```

```
X.I Professional-YAM
X$
Xcommand.
X.TP
X.B a
XConvert NL characters in the transmitted file to CR/LF.
XThis is done by the sender for XMODEM and YMODEM, by the receiver
Xfor ZMODEM.
X.TP
X.B b
X(ZMODEM) Binary override: transfer file without any translation.
X.TP
X.B "c COMMAND"
XSend COMMAND to the receiver for execution, return with COMMAND\'s exit status.
X.TP
X.B d
XChange all instances of "." to "/" in the transmitted pathname.
XThus, C.omenB0000 (which is unacceptable to MSDOS or CP/M)
Xis transmitted as C/omenB0000.
XIf the resultant filename has more than 8 characters in the stem,
Xa "." is inserted to allow a total of eleven.
X.TP
X.B E
XEscape only Ctrl-X control characters;
Xnormally XON, XOFF, CR-@-CR, and Ctrl-X are escaped.
X.TP
X.B e
XEscape all control characters;
Xnormally XON, XOFF, CR-@-CR, and Ctrl-X are escaped.
X.TP
X.B f
XSend Full pathname.
XNormally directory prefixes are stripped from the transmitted
Xfilename.
X.TP
X.B "i COMMAND"
XSend COMMAND to the receiver for execution, return Immediately
Xupon the receiving program's successful recption of the command.
X.TP
X.B k
X(XMODEM/YMODEM) Send files using 1024 byte blocks
Xrather than the default 128 byte blocks.
X1024 byte packets speed file transfers at high bit rates.
X(ZMODEM streams the data for the best possible throughput.)
X.TP
X.B "L N"
XUse ZMODEM sub-packets of length N.
XA larger N (32 <= N <= 1024) gives slightly higher throughput,
Xa smaller N speeds error recovery.
XThe default is 128 below 300 baud, 256 above 300 baud, or 1024 above 2400 baud.
X.TP
X.B "l N"
XWait for the receiver to acknowledge correct data every
```

```
X.B N
X(32 <= N <= 1024)
Xcharacters.
XThis may be used to avoid network overrun when XOFF flow control is lacking.
X.TP
X.B n
X(ZMODEM) Send each file if
Xdestination file does not exist.
XOverwrite destination file if
Xsource file is newer or longer than the destination file.
X.TP
X.B N
X(ZMODEM) Send each file if
Xdestination file does not exist.
XOverwrite destination file if
Xsource file has different length or date.
X.TP
X.B o
X(ZMODEM) Disable automatic selection of 32 bit CRC.
X.TP
X.B p
X(ZMODEM) Protect existing destination files by skipping transfer if the
Xdestination file exists.
X.TP
X.B q
XQuiet suppresses verbosity.
X.TP
X.B r
XResume interrupted file transfer.
XIf the source file is longer than the destination file,
Xthe transfer commences at the offset in the source file that equals
Xthe length of the destination file.
X.TP
X.B "t tim"
XChange timeout to
X.I tim
Xtenths of seconds.
X.TP
X.B u
XUnlink the file after successful transmission.
X.TP
X.B v
XVerbose
Xcauses a list of file
Xnames to be appended to
X/tmp/szlog .
XMore v's generate more output.
X.TP
X.B X
XSend a single file with
X.B XMODEM
Xor
X.B XMODEM-1k
```

```
Xprotocol.
X.TP
X.B y
XInstruct a ZMODEM receiving program to overwrite any existing file
Xwith the same name.
X.PD
X.SH EXAMPLES
X.ne 7
X.B "ZMODEM File Transfer"
X.br
X.B "$ sz -a *.c"
X.br
XThis single command transfers all .c files in the current Unix directory
Xwith conversion
X.RB ( -a )
Xto end of line conventions appropriate to the receiving environment.
XWith ZMODEM AutoDownload enabled, Professional-YAM  and ZCOMM
Xwill automatically recieve
Xthe files after performing a security check.
X
X.B "ZMODEM Command Download"
X.br
X cpszall:all
X    sz -c "c:;cd /yam/dist"
X    sz -ya $(YD)/*.me
X    sz -yqb y*.exe
X    sz -c "cd /yam"
X    sz -i "!insms"
X.br
XThis Makefile fragment uses
X.B sz
Xto issue commands to Professional-YAM to change current disk and directory.
XNext,
X.B sz
Xtransfers the
X.I .me
Xfiles from the $YD directory, commanding the receiver to overwrite the old files
Xand to convert from Unix end of line conventions to PC-DOS conventions.
XThe third line transfers some
X.I .exe
Xfiles.
XThe fourth and fifth lines command Pro-YAM to
Xchange directory and execute a PC-DOS batch file
X.I insms .
XSince the batch file takes considerable time, the
X.B "-i"
Xform is used to allow
X.B sz
Xto exit immediately.
X
X.B "XMODEM File Transfer"
X.br
X$
```

```
X.B "sz -Xa foo.c"
X.br
X.B "ESC"
X.br
X.B "rx foo.c"
X.br
XThe above three commands transfer a single file
Xfrom Unix to a PC and Crosstalk XVI 3.6,
Xtranslating Unix newlines to DOS CR/LF.
X
X32 bit CRC code courtesy Gary S. Brown.

X
XCompile time options required for various operating systems are described in
Xthe source file.
X.SH "VMS VERSION"
XThe VMS version does not transmit the file date.
XThe VMS version calculates the file length by reading the file
Xand counting the bytes.
X
XThe VMS version does not support YMODEM-g or ZMODEM.
X
XWhen VMS is lightly loaded, the response time may be too quick for MODEM7
Xunless the MODEM7
X.B "q"
Xmodifier is used.
X
XThe VMS C standard i/o package and RMS sometimes interact to modify
Xfile contents unexpectedly.
X.SH FILES
Xsz.c, rbsb.c, zm.c, zmodem.h source files
X
X/tmp/szlog stores debugging output (sz -vv)
X.SH "TESTING FEATURE"
XThe command "sz -T file"
Xexercises the
X.B Attn
Xsequence error recovery by commanding
Xerrors with unterminated packets.
XThe receiving program should complain five times about
Xbinary data packets being too long.
XEach time
X.B sz
```

```
Xis interrupted,
Xit should send a ZDATA header followed by another defective packet.
XIf the receiver does not detect five long data packets,
Xthe
X.B Attn
Xsequence is not interrupting the sender, and the
X.B Myattn
Xstring in
X.B sz.c
Xmust be modified.
X
XAfter 5 packets,
X.B sz
Xstops the "transfer" and
Xprints the total number of characters "sent" (Tcount).
XThe difference between Tcount and 5120 represents the number of characters
Xstored in various buffers when the Attn sequence is generated.
X.SH BUGS
XXMODEM transfers add up to 127 garbage bytes per file (1023 bytes with
XXMODEM-k).
XMost YMODEM programs use the file length transmitted at the beginning of the
Xtransfer to prune the file to the correct length; this may cause problems with
Xsource files that grow during the course of the transfer.
XThis problem does not pertain to ZMODEM transfers, which preserve the exact
Xfile length unconditionally.
X
XMost ZMODEM options are merely passed to the receiving program;
Xsome do not implement all these options.
X
XCircular buffering and a ZMODEM sliding window should be used
Xwhen input is from pipes instead of acknowledging frames each 1024 bytes.
XIf no files can be opened,
X.B sz
Xsends a ZMODEM command to echo a suitable complaint;
Xperhaps it should check for the presence of at least one accessible file before
Xgetting hot and bothered.
XThe test mode leaves a zero length file on the receiving system.
X
XSome high speed modems have a firmware bug that drops characters when the
Xdirection of high speed transmisson is reversed.
XThe environment variable ZNULLS may be used to specify the number of nulls to
Xsend before a ZDATA frame.
XValues of 101 for a 4.77 mHz PC and 124 for an AT are typical.
X.SH CWRU `ENHANCEMENTS'
XIf you compiled
X.B sz
Xwith the preprocessor symbol `CASE' defined then you will be able to use
Xthe following `features'.
X.sp 1
XIf sz if given the name of a directory as its arguement, then it will
Xsend the contents of the named directory, and of all the subdirectories.
XIf you need to send full path names, you still have to specify the
X.I -f
```

```
Xoption to
X.I sz.
X.sp 1
XIf you want to skip a branch of a directory, and do the rest, then you
Xmay use the
X.I -P name
Xoption, to `prune' off that branch of the tree. You may specify multiple
X.I -P name
Xoptions on the command line. They may appear anywhere on the command line,
Xso long as they appear before the name of a branch they prune, if thats
Xat the top level.
X.sp 1
XFor instance, let us suppose that you want to back up your unix system
Xto another system over the serial line, using zmodem. You  want to
Xback up all directories, except /tmp and say /usr/lib. Then you would
Xissue the following command:
X.sp 1
X.ce
Xsz -f -P /tmp -P /usr/lib /
X.sp 1
Xand go away for a looooong time!
X.sp 1
XThe CWRU `enhancements' use Berkeley Unix specific code, and have been
Xtested only under BSD4.3. When making
X.I sz
Xplease make sure that you are using the appropriate flavor of Unix, before
Xdefining the pre processor symbol `CASE'.

X     *   Examine each argument given to expandargs()
X     *   If it is a directory, then expand it
X     *   to all its component files, recursively
X     *   till you bottom out.
X     *   If it is not a directory, then just pass it on.
X     *
X     *   Inputs: routine, argc, argv
X     *   Outputs: nargc, nargv (calls routine(nargc, nargv))
X     *   To test: compile with -DTEST
X     *         define MWC if using Mark Williams C
X     *         run with a directory as an arg
X     *   Author: JRB   bammi@mandrill.ces.CWRU.edu
X     *   Requirements: Mark Williams C or Alcyon C
X     *        Wants lots of Dynamic memory. It
X     *        all depends upon how many files you
X     *        have. Use the -P option to prune
```

```
X     *       out subdirectories and do things
X     *       one at a time, if you keep running
X     *       out of memory.
X     *       With Mark Williams i use _stksize = 128K
X     *       With Alcyon i use memory model 2 (half of
X     *       of avail memory) in GEMSTART.S
X     *
X          *      WARNINGS: Be CAREFUL about the 40 folder bug. Use
X     *             GEMBOOT or FOLDRXXX when dealing with
X     *           a deeply nested file structure.
X     *
X     *   Added -P name prune option at the suggestion of dietz@zhmti
X     *   Multiple -P's may be given on the command line.
X     *   -P name may be given anywhere on the command line. -P name
X     *   will prune the subdirectories named as arguement to -P.
X     *   ie: when the program is decending the file hierarchy it
X     *   will not visit the pruned branches.
X     *   NOTE that the option is -P and not -p
X     *         (-p is a valid sz option).
X     *   NOTE that the arguement given to -P can be the name
X     *   of a file or a directory. In case it is a file,
X     *   that file is skipped.
X     *
X     */

X/*
X *  ATARI ST series implementation notes:
X *
X *       - the following command line options were removed as they
X *         were either  not applicable to the ST environment or
X *         were not deemed reasonable (by me - ofcourse).
X *            1    Not Applicable here as we have a seperate
```

```
X *               serial port.
X *          7    In this day and age? Forget it, get another m/c.
X *          a/b  Ascii/Binary - the receive mode (if not
X *               over-ridden by the sender) is automatically
X *               selected depending on the extention given
X *               in the incoming file name. This idea was
X *               present in earlier rz/sz, i wonder why such
X *               a convenient feature was dropped (Chuck ??).
X *               This feature is relevant to ZMODEM only in rz,
X *               as the sender determines the file mode in
X *               XMODEM/YMODEM transfers.
X *             B Note that `B' has a special meaning.
X *               Specifying -B will force override to
X *               binary mode for each incoming file. Useful
X *               when doing St-to-St transfers.
X *          D    There is no /dev/null on the ST's
X *          u    not applicable to TOS. Upper and lower
X *               case file names are the same. All the
X *               applicable routines like uncap() and
X *               IsAnyLower() were zapped.
X *
X *      - The    [-][v]rzCOMMAND style of invocation was dropped
X *        as there is no good way to do pipes without the
X *        microRtx kernal. All references to Pipe and popen()
X *        were zapped.
X *      - Verbose is always set to 2 by automatically, as we know that
X *        stdout != stderr. This can be overridden
X *        by specifying -q to ensure that Verbose = 0
X *      - The idea of a PUBDIR and Restricted paths in the origonal
X *        code  was dropped totally as it is not applicable
X *        to the single owner ST environment. 1 man 1 machine.
X *      - CRCTABLE is default always, hey we have plenty of memory!.
X *      - LOGFILE renamed to 'rzlog/szlog' as we don't always have
X *        a meaningful environment to pick up TMPDIR from (like when
X *        running from the desktop).
X *         - When a subdirectory in an incoming path name is not
X *        present it is created.
X *      - The file mode transmitted is 0S00 where S is derived from
X *        the Read/Write attribute of the file on the ST
X *      - When a file mode is received, only the owner bits are
X *        are checked. If it was read only (r--) on the Unix sytem
X *        then it is given read only attribute on the ST, read-write
X *        otherwise.
X *      - Of course all the I/O was completely redone on the ST.
X *      - You will find two versions of VARARGS routines like log,
X *        one that takes int args, and the other that takes long
X *        (address) args, since sizeof(int) != sizeof(long)
X *        and sizeof(int) != sizeof(pointer) on the ST.
X *
X *  ST v1.01
X *   added support for 32 bit CRC's for Zmodem ++jrb
X *
X *  ST v1.2
```

```
X *   added -B ++jrb
X *   added all the recursive stuff
X *   added remote
X */
X
X/*% cc -DNFGVMIN -DCRCTABLE -K -O % -o rz; size rz

X
X
X 1. ROSETTA STONE
X
X Here are some definitions which reflect the current vernacular
X in the computer media. The attempt here is identify the file
X transfer protocol rather than specific programs.
X
X XMODEM refers to the original 1979 file transfer etiquette
X introduced by Ward Christensen's 1979 MODEM2 program. It's also
X called the MODEM or MODEM2 protocol. Some who are unaware of MODEM7's
X unusual batch file mode call it MODEM7. Other aliases include "CP/M
X Users's Group" and "TERM II FTP 3". This protocol is supported by
X every serious communications program because of its universality,
X simplicity, and reasonable performance.
X
X XMODEM/CRC replaces XMODEM's 1 byte checksum with a two byte Cyclical
X Redundancy Check (CRC-16), giving modern error detection
X protection.
X
X XMODEM-1k Refers to the XMODEM/CRC protocol with 1024 byte data blocks.
X
X YMODEM refers to the XMODEM/CRC (optional 1k blocks) protocol with the
X batch transmission described below.
X
X ZMODEM uses familiar XMODEM/CRC and YMODEM technology in a
X new protocol that provides reliability, throughput, file
X management, and user amenities appropriate to contemporary
X data communications.
X
X
X 2. YET ANOTHER PROTOCOL?
X
X Since its development half a decade ago, the Ward Christensen modem
X protocol has enabled a wide variety of computer systems to interchange
X data. There is hardly a communications program that doesn't at least
X claim to support this protocol.
X
X Recent advances in computing, modems and networking have
X revealed a number of weaknesses in the original protocol:
X
X + The short block length caused throughput to suffer when used with
X timesharing systems, packet switched networks, satellite circuits,
X and buffered (error correcting) modems.

X
X + The 8 bit arithmetic checksum and other aspects allowed line
X impairments to interfere with dependable, accurate transfers.
X
X + Only one file could be sent per command. The file name had to be
X given twice, first to the sending program and then again to the
X receiving program.
X
X + The transmitted file could accumulate as many as 127 extraneous
X bytes.
X
X
X
X Chapter 2
X
X
X
X
X
X
X X/YMODEM Protocol Reference 09-11-86 3
X
X
X
X + The modification date of the file was lost.
X
X A number of other protocols have been developed over the
X years, but none have displaced XMODEM to date:
X
X + Lack of public domain documentation and example programs have kept
X proprietary protocols such as MNP, Blast, and others
X tightly bound to the fortunes of their suppliers.
X
X + Complexity discourages the widespread application of BISYNC, SDLC,
X HDLC, X.25, and X.PC protocols.
X
X + Performance compromises and moderate complexity have limited the
X popularity of the Kermit protocol, which was developed to allow file
X transfers in environments hostile to XMODEM.
X
X The XMODEM protocol extensions and YMODEM Batch address these
X weaknesses while maintaining XMODEM's simplicity.
X
X YMODEM is supported by the public domain programs YAM (CP/M),
X YAM(CP/M-86), YAM(CCPM-86), IMP (CP/M), KMD (CP/M), rz/sz (Unix, Xenix,
X VMS, Berkeley Unix, Venix, Xenix, Coherent, IDRIS, Regulus). Commerical
X implementations include MIRROR, and Professional-YAM.[1] Communications
X programs supporting these extensions have been in use since 1981.
X
X The 1k packet length (XMODEM-1k) described below may be used in
X conjunction with YMODEM Batch Protocol, or with single file transfers
X identical to the XMODEM/CRC protocol except for minimal
X changes to support 1k packets.

X
X	Another extension is simply called the g option. It provides maximum
X	throughput when used with end to end error correcting media,
X	such as X.PC and error correcting modems, including the emerging
X	9600 bps units by Electronic Vaults and others.
X
X	To complete this tome, Ward Christensen's original protocol document and
X	John Byrns's CRC-16 document are included for reference.
X
X	References to the MODEM or MODEM7 protocol have been changed
X	to XMODEM to accommodate the vernacular. In Australia, it is
X	properly called the Christensen Protocol.

X
X	2.1 Some Messages from the Pioneer
X
X	#: 130940 S0/Communications 25-Apr-85 18:38:47
X	Sb: my protocol
X	Fm: Ward Christensen 76703,302 (EDITED)
X	To: all
X
X	Be aware the article[2] DID quote me correctly in terms of the
X	phrases like "not robust", etc.
X
X	It was a quick hack I threw together, very unplanned (like
X	everything I do), to satisfy a personal need to communicate with
X	"some other" people.
X
X	ONLY the fact that it was done in 8/77, and that I put it in the public
X	domain immediately, made it become the standard that it is.

X
X	I think its time for me to
X
X	(1) document it; (people call me and say "my product is going
X	 to include it - what can I 'reference'", or "I'm writing a
X	 paper on it, what do I put in the bibliography") and
X
X	(2) propose an "incremental extension" to it, which might take
X	 "exactly" the form of Chuck Forsberg's YAM protocol. He
X	 wrote YAM in C for CP/M and put it in the public domain,
X	 and wrote a batch protocol for Unix[3] called rb and sb
X	 (receive batch, send batch), which was basically XMODEM with
X	 (a) a record 0 containing filename date time and size
X	 (b) a 1K block size option
X	 (c) CRC-16.
X
X	He did some clever programming to detect false ACK or EOT, but basically
X	left them the same.
X
X	People who suggest I make SIGNIFICANT changes to the protocol,
X	such as "full duplex", "multiple outstanding blocks", "multiple
X	destinations", etc etc don't understand that the incredible
X	simplicity of the protocol is one of the reasons it survived to
X	this day in as many machines and programs as it may be found in!
X
X	Consider the PC-NET group back in '77 or so - documenting to
X	beat the band
X	- THEY had a protocol, but it was "extremely complex", because
X	 it tried to be "all things to all people" - i.e. send binary
X	 files on a 7-bit system, etc. I was not that "benevolent". I
X	 (emphasize > I <) had an 8-bit UART,
X
X
X	----------
X
X	 2. Infoworld April 29 p. 16
X
X	 3. VAX/VMS versions of these programs are also available.

X
X
X	Chapter 2
X
X
X
X
X
X
X
X	X/YMODEM Protocol Reference	09-11-86	5
X
X

X
X	so "my protocol was an 8-bit protocol", and I would just say "sorry" to
X	people who were held back by 7-bit limitations. ...
X
X	Block size: Chuck Forsberg created an extension of my protocol,
X	called YAM, which is also supported via his public domain
X	programs for UNIX called rb and sb - receive batch and send
X	batch. They cleverly send a "block 0" which contains the
X	filename, date, time, and size. Unfortunately, its UNIX style,
X	and is abit weird[4] - octal numbers, etc. BUT, it is a nice way
X	to overcome the kludgy "echo the chars of the name" introduced
X	with MODEM7. Further, chuck uses CRC-16 and optional 1K blocks.
X	Thus the record 0, 1K, and CRC, make it a "pretty slick new
X	protocol" which is not significantly different from my own.
X
X	Also, there is a catchy name - YMODEM. That means to some
X	that it is the "next thing after XMODEM", and to others that it
X	is the Y(am)MODEM protocol. I don't want to emphasize that too
X	much - out of fear that other mfgrs might think it is a
X	"competitive" protocol, rather than an "unaffiliated" protocol.
X	Chuck is currently selling a much-enhanced version of his
X	CP/M-80 C program YAM, calling it Professional Yam, and its
X	for the PC - I'm using it right now. VERY slick! 32K capture buffer,
X	script, scrolling, previously captured text search, plus
X	built-in commands for just about everything - directory (sorted
X	every which way), XMODEM, YMODEM, KERMIT, and ASCII file
X	upload/download, etc. You can program it to "behave" with most
X	any system - for example when trying a number for CIS it detects
X	the "busy" string back from the modem and substitutes a diff
X	phone # into the dialing string and branches back to try it.
X
X
X
X	3. XMODEM PROTOCOL ENHANCEMENTS
X
X	This chapter discusses the protocol extensions to Ward Christensen's
X	1982 XMODEM protocol description document.
X
X	The original document recommends the user be asked whether to continue
X	trying or abort after 10 retries. Most programs no longer ask the
X	operator whether he wishes to keep retrying. Virtually all correctable
X	errors are corrected within the first few retransmissions. If
X	the line is so bad that ten attempts are insufficient, there is
X	a significant danger of undetected errors. If the connection is
X	that bad, it's better to redial for a better connection, or
X	mail a floppy disk.
X
X
X
X
X
X	----------
X

X   4. The file length, time, and file mode are optional.The pathname and
X   file length may be sent alone if desired.

X
X
X
X
X
X
X
X   X/YMODEM Protocol Reference   09-11-86   6
X
X
X
X   3.1 Graceful Abort
X
X   The YAM and Professional-YAM X/YMODEM routines recognize a
X   sequence of two consecutive CAN (Hex 18) characters without modem
X   errors (overrun, framing, etc.) as a transfer abort command. This
X   sequence is recognized when YAM is waiting for the beginning of a
X   packet or for an acknowledge to one that has been sent. The
X   check for two consecutive CAN characters virtually eliminates the
X   possibility of a line hit aborting the transfer. YAM sends
X   eight CAN characters when it aborts an XMODEM, YMODEM, or ZMODEM
X   protocol file transfer. Pro-YAM then sends eight backspaces to delete
X   the CAN characters from the remote's keyboard input buffer, in
X   case the remote had already aborted the transfer and was
X   awaiting a keyboarded command.
X
X
X   3.2 CRC-16 Option
X
X   The XMODEM protocol uses an optional two character CRC-16
X   instead of the one character arithmetic checksum used by the original
X   protocol and by most commercial implementations. CRC-16
X   guarantees detection of all single and double bit errors, all errors
X   with an odd number of error bits, all burst errors of length 16 or
X   less, 99.9969% of all 17-bit error bursts, and 99.9984 per cent
X   of all possible longer error bursts. By contrast, a double bit
X   error, or a burst error of 9 bits or more can sneak past the
X   XMODEM protocol arithmetic checksum.
X
X   The XMODEM/CRC protocol is similar to the XMODEM protocol,
X   except that the receiver specifies CRC-16 by sending C (Hex
X   43) instead of NAK when requesting the FIRST packet. A two
X   byte CRC is sent in place of the one byte arithmetic checksum.
X
X   YAM's c option to the r command enables CRC-16 in single file
X   reception, corresponding to the original implementation in the

X MODEM7 series programs. This remains the default because many
X commercial communications programs and bulletin board systems still do
X not support CRC-16, especially those written in Basic or Pascal.
X
X XMODEM protocol with CRC is accurate provided both sender and
X receiver both report a successful transmission. The protocol is robust
X in the presence of characters lost by buffer overloading on
X timesharing systems.
X
X The single character ACK/NAK responses generated by the
X receiving program adapt well to split speed modems, where the reverse
X channel is limited to ten per cent or less of he main channel's speed.
X
X XMODEM and YMODEM are half duplex protocols which do not attempt to
X transmit information and control signals in both directions at the same
X time. This avoids buffer overrun problems that have been reported by
X users attempting to exploit full duplex asynchronous file transfer
X protocols such as Blast.
X
X Professional-YAM adds several proprietary logic enhancements to XMODEM's
X
X

X
X
X
X error detection and recovery. These compatible enhancements eliminate
X most of the bad file transfers other programs make when using
X the XMODEM protocol under less than ideal conditions.
X
X
X 3.3 XMODEM-1k 1024 Byte Packet
X
X The choice to use 1024 byte packets is expressed to the sending
X program on its command line or selection menu.[1] 1024 byte packets
X improve throughput in many applications, but some environments cannot
X accept 1024 byte bursts, especially minicomuters running 19.2kb
X ports.
X
X An STX (02) replaces the SOH (01) at the beginning of the transmitted
X block to notify the receiver of the longer packet length. The
X transmitted packet contains 1024 bytes of data. The receiver
X should be able to accept any mixture of 128 and 1024 byte
X packets. The packet number is incremented by one for each

X packet regardless of the packet length.
X
X The sender must not change between 128 and 1024 byte packet lengths if it
X has not received a valid ACK for the current packet. Failure to observe
X this restriction allows certain transmission errors to pass undetected.
X
X If 1024 byte packets are being used, it is possible for a file to "grow"
X up to the next multiple of 1024 bytes. This does not waste disk space if
X the allocation granularity is 1k or greater. With YMODEM batch
X transmission, the optional file length transmitted in the file
X name packet allows the receiver to discard the padding,
X preserving the exact file length and contents.
X
X 1024 byte packets may be used with batch file transmission or with single
X file transmission. CRC-16 should be used with the k option to preserve
X data integrity over phone lines. If a program wishes to enforce this
X recommendation, it should cancel the transfer, then issue an informative
X diagnostic message if the receiver requests checksum instead of CRC-16.
X Under no circumstances may a sending program use CRC-16 unless the
X receiver commands CRC-16.
X
X
X 4. YMODEM Batch File Transmission
X
X The YMODEM Batch protocol is an extension to the XMODEM/CRC protocol that
X allows 0 or more files to be transmitted with a single command. (Zero
X files may be sent if none of the requested files is accessible.) The
X design approach of the YMODEM Batch protocol is to use the
X normal routines for sending and receiving XMODEM packets in a
X layered fashion similar to
X
X

X
X      packet switching methods.
X
X      Why was it necessary to design a new batch protocol when one already
X      existed in MODEM7?[1] The batch file mode used by MODEM7 is unsuitable
X      because it does not permit full pathnames, file length, file date, or
X      other attribute information to be transmitted. Such a restrictive design,
X      hastily implemented with only CP/M in mind, would not have permitted
X      extensions to current areas of personal computing such as Unix, DOS, and
X      object oriented systems.  In addition, the MODEM7 batch file mode is
X      somewhat susceptible to transmission impairments.
X
X
X
X      ----------
X
X       1. The MODEM7 batch protocol transmitted CP/M FCB bytes f1...f8 and
X          t1...t3 one character at a time.  The receiver echoed these bytes as
X          received, one at a time.
X
X
X
X
X      Chapter  4                              XMODEM Protocol Enhancements
```

As in the case of single a file transfer, the receiver initiates batch file transmission by sending a "C" character (for CRC-16).

The sender opens the first file and sends packet number 0 with the following information.[2]

Only the pathname (file name) part is required for batch transfers.

To maintain upwards compatibility, all unused bytes in packet 0 must be set to null.

Pathname The pathname (conventionally, the file name) is sent as a null terminated ASCII string. This is the filename format used by the handle oriented MSDOS(TM) functions and C library fopen functions. An assembly language example follows:

```
DB      'foo.bar',0
```

No spaces are included in the pathname. Normally only the file name stem (no directory prefix) is transmitted unless the sender has selected YAM's f option to send the full pathname. The source drive (A:, B:, etc.) is never sent.

Filename Considerations:

+ File names should be translated to lower case unless the sending system supports upper/lower case file names. This is a convenience for users of systems (such as Unix) which store filenames in upper and lower case.

+ The receiver should accommodate file names in lower and upper case.

+ When transmitting files between different operating systems, file names must be acceptable to both the sender and receiving operating systems.

If directories are included, they are delimited by /; i.e., "subdir/foo" is acceptable, "subdir\foo" is not.

Length The file length and each of the succeeding fields are optional.[3] The length field is stored in the packet as a decimal string counting the number of data bytes in the file. The file length does not include any CPMEOF (^Z) or other

X garbage characters used to pad the last packet.
X
X
X ----------
X
X 2. Only the data part of the packet is described here.
X
X 3. Fields may not be skipped.
X
X
X
X
X Chapter 4 XMODEM Protocol Enhancements
X
X
X
X
X
X
X
X X/YMODEM Protocol Reference 09-11-86 10
X
X
X
X If the file being transmitted is growing during transmission, the
X length field should be set to at least the final expected file
X length, or not sent.
X
X The receiver stores the specified number of characters, discarding
X any padding added by the sender to fill up the last packet.
X
X Modification Date The mod date is optional, and the filename and length
X may be sent without requiring the mod date to be sent.
X
X Iff the modification date is sent, a single space separates the
X modification date from the file length.
X
X The mod date is sent as an octal number giving the time the contents
X of the file were last changed, measured in seconds from Jan 1 1970
X Universal Coordinated Time (GMT). A date of 0 implies the
X modification date is unknown and should be left as the date the file
X is received.
X
X This standard format was chosen to eliminate ambiguities
X arising from transfers between different time zones.
X
X Two Microsoft blunders complicate the use of modification dates in
X file transfers with MSDOS(TM) systems. The first is the lack of
X timezone standardization in MS-DOS. A file's creation time can not
X be known unless the timezone of the system that wrote the file[4] is
X known. Unix solved this problem (for planet Earth, anyway) by
X stamping files with Universal Time (GMT). Microsoft would have to
X include the timezone of origin in the directory entries, but does

X not. Professional-YAM gets around this problem by using the z
X parameter which is set to the number of minutes local time lags GMT.
X For files known to originate from a different timezone, the -zT
X option may be used to specify T as the timezone for an individual
X file transfer.
X
X The second problem is the lack of a separate file creation date in
X DOS. Since some backup schemes used with DOS rely on the file
X creation date to select files to be copied to the archive, back-
X dating the file modification date could interfere with the safety of
X the transferred files. For this reason, Pro-YAM does not modify the
X date of received files with the header information unless the d
X numeric parameter is non zero.
X
X
X
X
X
X ----------
X
X 4. Not necessarily that of the transmitting system!
X
X
X
X
X Chapter 4 XMODEM Protocol Enhancements
X
X
X
X
X
X
X
X X/YMODEM Protocol Reference 09-11-86 11
X
X
X
X Mode Iff the file mode is sent, a single space separates the file mode
X from the modification date. The file mode is stored as an octal
X string. Unless the file originated from a Unix system, the
X file mode is set to 0. rb(1) checks the file mode for the
X 0x8000 bit which indicates a Unix type regular file. Files
X with the 0x8000 bit set are assumed to have been sent from
X another Unix (or similar) system which uses the same file
X conventions. Such files are not translated in any way.
X
X
X Serial Number Iff the serial number is sent, a single space separates the
X serial number from the file mode. The serial number of the
X transmitting program is stored as an octal string.
X Programs which do not have a serial number should omit this
X field, or set it to 0. The receiver's use of this field is
X optional.

X
X
X Other Fields YMODEM was designed to allow additional header fields to be
X added as above without creating compatibility problems with older
X YMODEM programs. Please contact Omen Technology if other fields are
X needed for special application requirements.
X
X The rest of the packet is set to nulls. This is essential to preserve
X upward compatibility.[5]
X
X If the filename packet is received with a CRC or other error, a
X restrnsmission is requested. After the filename packet has been
X received, it is ACK'ed if the write open is successful. If the
X file cannot be opened for writing, the receiver cancels the
X transfer with CAN characters as described above.
X
X The receiver then initiates transfer of the file contents
X according to the standard XMODEM/CRC protocol.
X
X After the file contents have been transmitted, the receiver
X again asks for the next pathname. Transmission of a null
X pathname terminates batch file transmission. Note that
X transmission of no files is not necessarily an error. This is
X possible if none of the files requested of the sender could be
X opened for reading.
X
X In batch transmission, the receiver automatically requests CRC-16.
X
X The Unix programs sz(1) and rz(1) included in the source code file
X
X
X ----------
X
X 5. If, perchance, this information extends beyond 128 bytes (possible
X with Unix 4.2 BSD extended file names), the packet should be
X sent as a 1k packet as described above.

X
X KMD and IMP character sequence emitted by the receiver (CK) to
X automatically trigger the use of 1024 byte packets as an alternative to
X specifying this option on this command line. Although this two character
X sequence works well on single process micros in direct communication,
X timesharing systems and packet switched networks can separate the
X successive characters by several seconds, rendering this method
X unreliable.
X
X Sending programs may detect the CK sequence if the operating enviornment
X does not preclude reliable implementation.
X
X Receiving programs should retain the option of sending the
X standard YMODEM C (not CK) trigger with the standard 10 second
X timeout to insure compatibility with newer forms of
X telecommunications technology.
X
X
X
X 5. YMODEM-g File Transmission
X
X Developing technology is providing phone line data transmission at ever
X higher speeds using very specialized techniques. These high
X speed modems, as well as session protocols such as X.PC, provide

X high speed, error free communications at the expense of
X considerably increased delay time.
X
X This delay time is moderate compared to human interactions, but it
X cripples the throughput of most error correcting protocols.
X
X The g option to YMODEM has proven effective under these circumstances.
X The g option is driven by the receiver, which initiates the
X batch transfer by transmitting a G instead of C. When the
X sender recognizes the G, it bypasses the usual wait for an ACK
X to each transmitted packet, sending succeeding packets at full
X speed, subject to XOFF/XON or other flow control exerted by the medium.
X
X
X
X Chapter 5 XMODEM Protocol Enhancements
X
X
X
X
X
X
X
X X/YMODEM Protocol Reference 09-11-86 14
X
X
X
X The sender expects an inital G to initiate the transmission of a
X particular file, and also expects an ACK on the EOT sent at the end of
X each file. This synchronization allows the receiver time to open and
X close files as necessary.
X
X If an error is detected in a YMODEM-g transfer, the receiver aborts the
X transfer with the multiple CAN abort sequence. The ZMODEM protocol should
X be used in applications that require both streaming throughput and error
X recovery.

X
X
X
X 6.2 Transmission Medium Level Protocol
X
X Asynchronous, 8 data bits, no parity, one stop bit.
X
X The protocol imposes no restrictions on the contents of the data being
X transmitted. No control characters are looked for in the 128-byte data
X messages. Absolutely any kind of data may be sent - binary, ASCII, etc.
X The protocol has not formally been adopted to a 7-bit environment for the
X transmission of ASCII-only (or unpacked-hex) data , although it could be
X simply by having both ends agree to AND the protocol-dependent data with
X 7F hex before validating it. I specifically am referring to the
X checksum, and the block numbers and their ones- complement.
X

```
X      Those wishing to maintain compatibility of the CP/M file structure, i.e.
X      to allow modemming ASCII files to or from CP/M systems should follow this
X      data format:
X
X         + ASCII tabs used (09H); tabs set every 8.
X
X         + Lines terminated by CR/LF (0DH 0AH)
X
X         + End-of-file indicated by ^Z, 1AH. (one or more)
X
X         + Data is variable length, i.e. should be considered a continuous
X           stream of data bytes, broken into 128-byte chunks purely for the
X           purpose of transmission.
X
X         + A CP/M "peculiarity": If the data ends exactly on a 128-byte
X           boundary, i.e. CR in 127, and LF in 128, a subsequent sector
X           containing the ^Z EOF character(s) is optional, but is preferred.
X           Some utilities or user programs still do not handle EOF without ^Zs.

X         + The last block sent is no different from others, i.e.  there is no
X           "short block".
X              Figure 7.  XMODEM Message Block Level Protocol
X
X      Each block of the transfer looks like:
X            <SOH><blk #><255-blk #><--128 data bytes--><cksum>
X      in which:
X      <SOH>           = 01 hex
X      <blk #>         = binary number, starts at 01 increments by 1, and
X                wraps 0FFH to 00H (not to 01)
X      <255-blk #>   =   blk # after going thru 8080 "CMA" instr, i.e.
X                each bit complemented in the 8-bit block number.
X                Formally, this is the "ones complement".
X      <cksum>       = the sum of the data bytes only.  Toss any carry.

X
X
X
X      6.3  File Level Protocol
X
X      6.3.1  Common_to_Both_Sender_and_Receiver
X      All errors are retried 10 times.  For versions running with an operator
X      (i.e. NOT with XMODEM), a message is typed after 10 errors asking the
X      operator whether to "retry or quit".
X
X      Some versions of the protocol use <can>, ASCII ^X, to cancel
```

X transmission. This was never adopted as a standard, as having a
X single "abort" character makes the transmission susceptible to
X false termination due to an <ack> <nak> or <soh> being corrupted
X into a <can> and aborting transmission.
X
X The protocol may be considered "receiver driven", that is, the
X sender need not automatically re-transmit, although it does in
X the current implementations.
X
X
X 6.3.2 Receive_Program_Considerations
X The receiver has a 10-second timeout. It sends a <nak> every time it
X times out. The receiver's first timeout, which sends a <nak>,
X signals the transmitter to start. Optionally, the receiver
X could send a <nak> immediately, in case the sender was ready.
X This would save the initial 10 second timeout. However, the
X receiver MUST continue to timeout every 10 seconds in case the
X sender wasn't ready.
X
X Once into a receiving a block, the receiver goes into a
X one-second timeout for each character and the checksum. If the
X receiver wishes to <nak> a block for any reason (invalid header,
X timeout receiving data), it must wait for the line to clear.
X See "programming tips" for ideas.
X
X Synchronizing: If a valid block number is received, it will be: 1) the
X expected one, in which case everything is fine; or 2) a repeat of the
X previously received block. This should be considered OK, and only
X indicates that the receivers <ack> got glitched, and the sender re-
X transmitted; 3) any other block number indicates a fatal loss of
X synchronization, such as the rare case of the sender getting a
X line-glitch that looked like an <ack>. Abort the transmission,
X sending a <can>
X
X
X 6.3.3 Sending_program_considerations
X While waiting for transmission to begin, the sender has only a
X single very long timeout, say one minute. In the current
X protocol, the sender has a 10 second timeout before retrying. I
X suggest NOT doing this, and letting the protocol be completely
X receiver-driven. This will be compatible with existing programs.
X
X When the sender has no more data, it sends an <eot>, and awaits an <ack>,
X resending the <eot> if it doesn't get one. Again, the protocol could be
X receiver-driven, with the sender only having the high-level 1-minute
X timeout to abort.
X
X
X
X

Here is a sample of the data flow, sending a 3-block message.
It includes the two most common line hits - a garbaged block,
and an <ack> reply getting garbaged. <xx> represents the checksum byte.

Figure 8. Data flow including Error Recovery

```
SENDER                          RECEIVER
                        times out after 10 seconds,
                        <---            <nak>
<soh> 01 FE -data- <xx>      --->
                        <---            <ack>
<soh> 02 FD -data- xx        --->        (data gets line hit)
                        <---            <nak>
<soh> 02 FD -data- xx        --->
                        <---            <ack>
<soh> 03 FC -data- xx        --->
(ack gets garbaged)          <---            <ack>
<soh> 03 FC -data- xx        --->            <ack>
<eot>                        --->
                        <---       <anything except ack>
<eot>                        --->
                        <---            <ack>
(finished)
```

6.4 Programming Tips

+ The character-receive subroutine should be called with a parameter specifying the number of seconds to wait. The receiver should first call it with a time of 10, then <nak> and try again, 10 times.

  After receiving the <soh>, the receiver should call the character receive subroutine with a 1-second timeout, for the remainder of the message and the <cksum>. Since they are sent as a continuous stream, timing out of this implies a serious like glitch that caused, say, 127 characters to be seen instead of 128.

+ When the receiver wishes to <nak>, it should call a "PURGE" subroutine, to wait for the line to clear. Recall the sender tosses any characters in its UART buffer immediately upon completing sending a block, to ensure no glitches were mis-interpreted.

  The most common technique is for "PURGE" to call the character

X receive subroutine, specifying a 1-second timeout,[1] and looping
X back to PURGE until a timeout occurs. The <nak> is then sent,
X ensuring the other end will see it.
X
X
X ----------
X
X 1. These times should be adjusted for use with timesharing systems.
X
X
X
X
X Chapter 6 Xmodem Protocol Overview
X
X
X
X
X
X
X
X X/YMODEM Protocol Reference 09-11-86 18
X
X
X
X + You may wish to add code recommended by John Mahr to your character
X receive routine - to set an error flag if the UART shows framing
X error, or overrun. This will help catch a few more glitches - the
X most common of which is a hit in the high bits of the byte in two
X consecutive bytes. The <cksum> comes out OK since counting
X in 1-byte produces the same result of adding 80H + 80H as
X with adding 00H + 00H.
X
X
X
X 7. XMODEM/CRC Overview
X
X 1/13/85 by John Byrns -- CRC option.
X
X Please pass on any reports of errors in this document or suggestions for
X improvement to me via Ward's/CBBS at (312) 849-1132, or by voice at (312)
X 885-1105.
X
X The CRC used in the Modem Protocol is an alternate form of block check
X which provides more robust error detection than the original checksum.
X Andrew S. Tanenbaum says in his book, Computer Networks, that the CRC-
X CCITT used by the Modem Protocol will detect all single and double bit
X errors, all errors with an odd number of bits, all burst errors of length
X 16 or less, 99.997% of 17-bit error bursts, and 99.998% of 18-bit and
X longer bursts.
X
X The changes to the Modem Protocol to replace the checksum with
X the CRC are straight forward. If that were all that we did we
X would not be able to communicate between a program using the old

X checksum protocol and one using the new CRC protocol. An initial
X handshake was added to solve this problem. The handshake allows
X a receiving program with CRC capability to determine whether the
X sending program supports the CRC option, and to switch it to CRC
X mode if it does. This handshake is designed so that it will work
X properly with programs which implement only the original
X protocol. A description of this handshake is presented in section 10.
X
X Figure 9. Message Block Level Protocol, CRC mode
X
X Each block of the transfer in CRC mode looks like:
X <SOH><blk #><255-blk #><--128 data bytes--><CRC hi><CRC lo>
X in which:
X <SOH> = 01 hex
X <blk #> = binary number, starts at 01 increments by 1, and
X wraps 0FFH to 00H (not to 01)
X <255-blk #> = ones complement of blk #.
X <CRC hi> = byte containing the 8 hi order coefficients of the CRC.
X <CRC lo> = byte containing the 8 lo order coefficients of the CRC.

X
X
X
X
X X/YMODEM Protocol Reference 09-11-86 19
X
X
X
X 7.1 CRC Calculation
X
X 7.1.1 Formal_Definition
X To calculate the 16 bit CRC the message bits are considered to be the
X coefficients of a polynomial. This message polynomial is first multiplied
X by X^16 and then divided by the generator polynomial (X^16 + X^12 + X^5 +
X 1) using modulo two arithmetic. The remainder left after the division is
X the desired CRC. Since a message block in the Modem Protocol is 128 bytes
X or 1024 bits, the message polynomial will be of order X^1023.
X The hi order bit of the first byte of the message block is the
X coefficient of X^1023 in the message polynomial. The lo order
X bit of the last byte of the message block is the coefficient of
X X^0 in the message polynomial.
X
X Figure 10. Example of CRC Calculation written in C

X UPDCRC update routine from "rbsb.c". Refer to the source code for these
X programs (contained in RZSZ1.SHQ and RZSZ2.SHQ) for usage. A fast table
X driven macro is also included in this file.

```
X /* update CRC */
X unsigned short
X updcrc(c, crc)
X register c;
X register unsigned crc;
X {
X   register count;
X
X   for (count=8; --count>=0;) {
X           if (crc & 0x8000) {
X                   crc <<= 1;
X                   crc += (((c<<=1) & 0400)  !=  0);
X                   crc ^= 0x1021;
X           }
X           else {
X                   crc <<= 1;
X                   crc += (((c<<=1) & 0400)  !=  0);
X           }
X   }
X   return crc;
X }
```

X
X 7.2 CRC File Level Protocol Changes
X
X 7.2.1 Common_to_Both_Sender_and_Receiver
X The only change to the File Level Protocol for the CRC option is the
X initial handshake which is used to determine if both the sending and the
X receiving programs support the CRC mode. All Modem Programs
X should support the checksum mode for compatibility with older
X versions. A receiving program that wishes to receive in CRC
X mode implements the mode setting handshake by sending a <C> in
X place of the initial <nak>. If the sending program supports CRC
X mode it will recognize the <C> and will set itself into CRC
X mode, and respond by sending the first block as if a <nak> had
X been received. If the sending program does not support CRC mode it will
X
X
X

X not respond to the <C> at all. After the receiver has sent the
X <C> it will wait up to 3 seconds for the <soh> that starts the
X first block. If it receives a <soh> within 3 seconds it will
X assume the sender supports CRC mode and will proceed with the
X file exchange in CRC mode. If no <soh> is received within 3
X seconds the receiver will switch to checksum mode, send a <nak>,
X and proceed in checksum mode. If the receiver wishes to use
X checksum mode it should send an initial <nak> and the sending program
X should respond to the <nak> as defined in the original Modem Protocol.
X After the mode has been set by the initial <C> or <nak> the protocol
X follows the original Modem Protocol and is identical whether the checksum
X or CRC is being used.
X
X
X 7.2.2 Receive_Program_Considerations
X There are at least 4 things that can go wrong with the mode setting
X handshake.
X
X 1. the initial <C> can be garbled or lost.
X
X 2. the initial <soh> can be garbled.
X
X 3. the initial <C> can be changed to a <nak>.
X
X 4. the initial <nak> from a receiver which wants to receive
X in checksum can be changed to a <C>.
X
X The first problem can be solved if the receiver sends a second <C> after
X it times out the first time. This process can be repeated several times.
X It must not be repeated too many times before sending a <nak> and
X switching to checksum mode or a sending program without CRC support may
X time out and abort. Repeating the <C> will also fix the second problem if
X the sending program cooperates by responding as if a <nak> were received
X instead of ignoring the extra <C>.
X
X It is possible to fix problems 3 and 4 but probably not worth the trouble
X since they will occur very infrequently. They could be fixed by switching
X modes in either the sending or the receiving program after a large number
X of successive <nak>s. This solution would risk other problems however.
X
X
X 7.2.3 Sending_Program_Considerations
X The sending program should start in the checksum mode. This will insure
X compatibility with checksum only receiving programs. Anytime a <C> is
X received before the first <nak> or <ack> the sending program should set
X itself into CRC mode and respond as if a <nak> were received. The sender
X should respond to additional <C>s as if they were <nak>s until the first
X <ack> is received. This will assist the receiving program in determining
X the correct mode when the <soh> is lost or garbled. After the first <ack>
X is received the sending program should ignore <C>s.
X
X
X

X
X
X
X 7.3 Data Flow Examples with CRC Option
X
X Here is a data flow example for the case where the receiver requests
X transmission in the CRC mode but the sender does not support the CRC
X option. This example also includes various transmission errors. <xx>
X represents the checksum byte.
